

A NOTE ON A QUESTION OF J. NEKOVÁŘ AND THE BIRCH AND SWINNERTON-DYER CONJECTURE

KEN ONO

ABSTRACT. If D is a square-free integer, then let $E(D)$ denote the elliptic curve over \mathbb{Q} given by the equation

$$(1) \quad E(D) : \quad Dy^2 = 4x^3 - 27.$$

Let $L(E(D), s)$ denote the Hasse-Weil L -function of $E(D)$, and let $L^*(E(D), 1)$ denote the ‘algebraic part’ of the central critical value $L(E(D), 1)$. Using a theorem of Sturm, we verify a congruence conjectured by J. Nekovář. By his work, if $S(3, E(D))$ denotes the 3-Selmer group of $E(D)$ and $D \neq 1$ is a square-free integer with $|D| \equiv 1 \pmod{3}$, then we find that

$$L^*(E(D), 1) \not\equiv 0 \pmod{3} \iff S(3, E(D)) = 0.$$

If $D \neq 1$ is a square-free integer, then $E(D)$ is the D -quadratic twist of the Fermat cubic $x^3 + y^3 = 1$. J. Nekovář explicitly computed the 3-Selmer ranks of these elliptic curves, and verified the ‘mod 3’ part of the Birch and Swinnerton-Dyer Conjecture for most of these curves when $|D| \equiv 1 \pmod{3}$ using Waldspurger’s theorem on the Shimura correspondence.

If $q := e^{2\pi iz}$, and $\eta(z)$ and $\Theta(z)$ denote the usual weight 1/2 modular forms

$$\eta(z) := q^{1/24} \prod_{n=1}^{\infty} (1 - q^n) \quad \text{and} \quad \Theta(z) := 1 + 2 \sum_{n=1}^{\infty} q^{n^2},$$

then define $a(n)$ by $\sum_{n=1}^{\infty} a(n)q^n := \eta^2(3z)\eta^2(9z) \in S_2(\Gamma_0(27))$. The Hasse-Weil L -function $L(E(D), s)$ is given by

$$(2) \quad L(E(D), s) := \sum_{n=1}^{\infty} \frac{a(n) \binom{D}{n}}{n^s}.$$

Furthermore let $L^*(E(D), 1)$ denote the ‘algebraic part’ of the critical value $L(E(D), 1)$. In particular it is given by

$$(3) \quad L^*(E(D), 1) := \frac{L(E(D), 1)}{\Omega(E(D)) \prod_p c_p}$$

where $\Omega(E(D))$ is the real period of $E(D)$, and $\prod_p c_p$ is the ‘Tamagawa factor.’ In particular if p is an odd prime and $S(p, E(D))$ denotes the p -Selmer group of $E(D)$, then the Birch and Swinnerton-Dyer Conjecture predicts that

$$(4) \quad L^*(E(D), 1) \not\equiv 0 \pmod{p} \Rightarrow S(p, E(D)) = 0.$$

Since the $E(D)$ are curves with complex multiplication by $\mathbb{Q}(\sqrt{-3})$, a theorem of Rubin [R] implies that

$$L^*(E(D), 1) \not\equiv 0 \pmod{p} \Rightarrow S(p, E(D)) = 0$$

for primes $p \geq 5$.

If D is square-free and $|D| \equiv 2 \pmod{3}$, then $L(E(D), 1) = L^*(E(D), 1) = 0$, and so we restrict our attention to those square-free D where $|D| \equiv 1 \pmod{3}$. J. Nekovář computed the 3-Selmer ranks of $E(D)$ and verified (4) when $p = 3$ [Cor. 7.5, N] for all such D except when

$$(5) \quad 0 > D \equiv 5 \pmod{8} \quad \text{and} \quad 1 < D \equiv 1 \pmod{8}.$$

He explicitly computed 3-Selmer ranks using ideal class groups of suitable quadratic fields, and employed elementary congruences between certain Fourier coefficients of weight $3/2$ cusp forms and class numbers.

To prove (4) when $p = 3$ for the remaining cases (5), Nekovář noted that it suffices to prove:

Conjecture [(7.1), N]. Define $a_1(n)$ and $a_2(n)$ by

$$\sum_{n=1}^{\infty} a_1(n)q^n := \eta(6z)\eta(18z)\Theta(3z)$$

$$\sum_{n=1}^{\infty} a_2(n)q^n := \eta(6z)\eta(18z)\Theta(9z).$$

If $h(-n)$ denotes the class number of the quadratic field $\mathbb{Q}(\sqrt{-n})$, then

- (i) $\frac{a_1(D)}{3} \equiv -h(-D) \pmod{3}$ if $D \equiv 19 \pmod{24}$ is square-free,
- (ii) $\frac{a_2(D)}{3} \equiv -h(-3D) \pmod{3}$ if $1 < D \equiv 1 \pmod{24}$ is square-free.

Theorem. *Conjecture (7.1) is true.*

Corollary. *If $D \neq 1$ is a square-free integer for which $|D| \equiv 1 \pmod{3}$, then*

$$L^*(E(D), 1) \not\equiv 0 \pmod{3} \iff S(3, E(D)) = 0.$$

Proof of Corollary. This follows immediately from Theorem 4.6, Proposition 7.1, and Proposition 7.2 in [N]. □

Proof of Theorem. Throughout k denotes a non-negative integer. We begin with a well known fact. If $g(z) := \sum_{n=1}^{\infty} c(n)q^n \in M_{k+\frac{1}{2}}(\Gamma_1(N))$, then

$$(6) \quad g_{r,t}(z) := \sum_{n \equiv r \pmod{t}} c(n)q^n \in M_{k+\frac{1}{2}}\left(\Gamma_1\left(\frac{Nt^2}{\gcd(r,t)}\right)\right).$$

We recall a special case of a theorem of Sturm [S]. Suppose that $h(z) := \sum_{n=0}^{\infty} d(n)q^n \in M_k(\Gamma_1(M))$ has integer Fourier coefficients. Sturm proved that

$$(7) \quad h(z) \equiv 0 \pmod{S} \iff \text{Ord}_S(h(z)) > \frac{k}{12}M^2 \prod_{p|M} \left(1 - \frac{1}{p^2}\right)$$

where $\text{Ord}_S(h(z)) := \min_n(d(n) \not\equiv 0 \pmod{S})$. If $i(z) := \sum_{n=0}^{\infty} e(n)q^n \in M_{k+\frac{1}{2}}(\Gamma_1(M))$ has integer coefficients, then by applying (7) to $i(z)\Theta(z)$ we find that

$$(8) \quad i(z) \equiv 0 \pmod{S} \iff \text{Ord}_S(i(z)) > \frac{k+1}{12}M^2 \prod_{p|M} \left(1 - \frac{1}{p^2}\right).$$

Case (i): The form $\sum_{n=1}^{\infty} a_1(n)q^n$ is in $S_{\frac{3}{2}}(\Gamma_0(108), \chi_0)$, where χ_0 is the trivial character, and has the property that $a_1(n) = 0$ if $n \not\equiv 1 \pmod{3}$. Therefore by (6) we find that

$$f_1(z) := \sum_{n \equiv 3 \pmod{8}} a_1(n)q^n = \sum_{n \equiv 19 \pmod{24}} a_1(n)q^n = -3q^{19} + 6q^{43} - \dots \in S_{\frac{3}{2}}(\Gamma_1(108 \cdot 8^2)).$$

Similarly if $\Theta^3(z) := \sum_{n=0}^{\infty} r_1(n)q^n \in M_{\frac{3}{2}}(4)$, then by (6)

$$t_1(z) := \sum_{n \equiv 19 \pmod{24}} r_1(n)q^n = 24q^{19} + 24q^{43} + 24q^{67} + 48q^{91} + \dots \in M_{\frac{3}{2}}(4 \cdot 24^2).$$

It is easy to verify that $f_1(z) \equiv 0 \pmod{3}$ and $t_1(z) \equiv 0 \pmod{24}$, and with these observations define $i_1(z)$ by

$$i_1(z) := \frac{f_1(z)}{3} + \frac{t_1(z)}{24} = 3q^{43} + 3q^{91} + 6q^{139} + \cdots \in M_{\frac{3}{2}}(\Gamma_1(6912)).$$

A computation verified the congruence $i_1(z) \equiv 0 \pmod{3}$ for the first 5,400,000 terms, and so by (8)

$$\frac{a_1(n)}{3} \equiv -\frac{r_1(n)}{24} \pmod{3}$$

for every integer $n \equiv 19 \pmod{24}$. Conjecture 7.1 (i) follows immediately by Gauss' theorem that if $n \equiv 19 \pmod{24}$ is square-free, then $r_1(n) = 24h(-n)$ (see [J]).

Case (ii): The form $\sum_{n=1}^{\infty} a_2(n)q^n \in S_{\frac{3}{2}}(\Gamma_0(108), \chi_{-3})$ has the property that $a_2(n) = 0$ if $n \not\equiv 1 \pmod{3}$. Therefore by (6) it turns out that

$$f_2(z) := \sum_{n \equiv 1 \pmod{8}} a_2(n)q^n = \sum_{n \equiv 1 \pmod{24}} a_2(n)q^n = q + q^{25} - 2q^{49} - \cdots \in S_{\frac{3}{2}}(\Gamma_1(108 \cdot 8^2)).$$

Similarly if $\sum_{n=0}^{\infty} r_2(n)q^n := \Theta^2(z)\Theta(3z) \in M_{\frac{3}{2}}(\Gamma_1(12))$, then by (6)

$$t_2(z) := \sum_{n \equiv 1 \pmod{24}} r_2(n)q^n = 4q + 28q^{25} + 28q^{49} + 48q^{73} + \cdots \in M_{\frac{3}{2}}(\Gamma_1(12 \cdot 24^2)).$$

It is easy to see that $t_2(z) \equiv 0 \pmod{4}$, and so the modular form

$$f_2(z) + \frac{t_2(z)}{4} = 2q + 8q^{25} + 5q^{49} + 9q^{73} + 9q^{97} + \cdots \in M_{\frac{3}{2}}(\Gamma_1(12 \cdot 24^2)),$$

and modulo 9 its first few terms are

$$f_2(z) + \frac{t_2(z)}{4} \equiv 2q + 8q^{25} + 5q^{49} + 5q^{121} + \cdots \pmod{9}.$$

Although it is unnecessary, we recall the following eta-function identity

$$\frac{\eta^5(6z)}{\eta^2(3z)} = \sum_{1 \leq n \equiv 1,2 \pmod{6}} nq^{n^2} - \sum_{0 < n \equiv 4,5 \pmod{6}} nq^{n^2} \in S_{\frac{3}{2}}(\Gamma_1(144)).$$

By (6) it is easy to see that

$$j_2(z) := \sum_{1 \leq n \equiv 1 \pmod{6}} nq^{n^2} - \sum_{0 < n \equiv 5 \pmod{6}} nq^{n^2} \in S_{\frac{3}{2}}(\Gamma_1(144 \cdot 4)).$$

Define the form $i_2(z) \in M_{\frac{3}{2}}(\Gamma_1(6912))$ by

$$i_2(z) := f_2(z) + \frac{t_2(z)}{4} - 2j_2(z) = 18q^{25} - 9q^{49} + 9q^{73} + 9q^{97} + \dots$$

After computing the first 5,400,000 terms, by (8) we find that $i_2(z) \equiv 0 \pmod{9}$. In particular if $1 < n \equiv 1 \pmod{24}$ is square-free, then

$$(9) \quad a_2(n) + \frac{r_2(n)}{4} \equiv 0 \pmod{9}.$$

Since $r_2(n) = \#\{x^2 + y^2 + 3z^2 = n \mid x, y, z \in \mathbb{Z}\}$, and the ternary form $x^2 + y^2 + 3z^2$ is in a genus with a single class, by [Th. 86, J] it turns out that $r_2(n) = 12h(-3n)$ if $1 < n \equiv 1 \pmod{24}$ is square-free. Therefore for such n it is easy to see by (9) that

$$\frac{a_2(n)}{3} \equiv -h(-3n) \pmod{3}.$$

□

Remark. Using a theorem of Davenport and Heilbronn, as refined by Horie and Nakagawa (see [D-H], [H-N]), it is easy to deduce that

$$\liminf_{x \rightarrow \infty} \frac{\#\{|D| < x \mid \text{square-free } |D| \equiv 1 \pmod{3}, \text{ with } S(3, E(D)) = 0\}}{\#\{|D| < x \mid \text{square-free } |D| \equiv 1 \pmod{3}\}} \geq \frac{1}{2}.$$

In particular for such D the curves $E(D)$ have rank zero at least half the time. These ideas have been employed by James [Ja], Horie and Nakagawa [H-N], and Wong [W] to deduce that a positive proportion of certain families of twists of fixed elliptic curves have rank zero.

ACKNOWLEDGEMENTS

The author is indebted to W. Galway whose computations verified the conjectured congruences.
