## Abstract

We study the impact of reforms that introduced more stringent, biometric ID requirements into India's largest social protection program, using large-scale randomized and natural experiments. Corruption fell but with substantial costs to legitimate beneficiaries, 1.5-2 million of whom lost access to benefits at some point during the reforms. At the same time, adverse effects appear to have been driven primarily by decisions about the way the transition was managed, illustrating both the risks of rapid reforms, and how the impacts of promising new technologies can be highly sensitive to the protocols governing their use.

# 1 Introduction

From accessing welfare benefits to casting votes, citizens often have to establish their identity to interact with the state. Politics around the world often debate how stringent ID requirements for these interactions should be. The core design issue is how to manage the trade-off between errors of *inclusion* whereby benefits are granted to ineligible people, against errors of *exclusion* whereby legitimate beneficiaries are denied benefits to which they are legally entitled. Managing this trade-off is especially challenging in settings with corrupt intermediaries who can exacerbate both types of errors: adding fake beneficiaries to rosters, for example, or diverting benefits and denying them to legitimate ones.

One approach to improving this trade-off is to invest in more sophisticated identification technology. Historically states have done this gradually as they develop (Scott, 1998), but there is a growing push to accelerate the process in developing countries.<sup>1</sup> During the past two decades in particular “the number of national identification and similar programs has grown exponentially... to the point where almost all developing countries have at least one such program” (Gelb and Metz, 2018). Around two-thirds of these programs use biometric technology, reflecting the view that this provides more reliable authentication than alternatives, particularly in settings with low levels of literacy and numeracy.

A leading case is India, where the government has issued unique identification (“Aadhaar”) numbers, linked to biometric records, to over 1.24 billion people and is now integrating Aadhaar-based biometric authentication into a range of applications. The question of whether Aadhaar should be mandated to receive welfare benefits has been highly controversial, and contested all the way to India’s Supreme Court. Proponents, including the government, point to reduced spending on welfare programs post-integration (as documented for example by Barnwal (2019)) to argue that it reduces fraud and corruption. Critics point to documented cases of beneficiaries excluded as a result of such integration to argue that it denies people their legal entitlements and thus “undermines the right to life” (Khera, 2017).

This paper contributes evidence to this debate and to the broader discussion on identity standards for participating in public programs. We study the introduction of Aadhaar as a requirement to collect benefits in the Public Distribution System (PDS) in the state of Jharkhand. The PDS is India’s flagship program for providing food security to the poor: it is India’s largest welfare program, and accounts for roughly 1% of GDP. PDS beneficiaries are entitled to purchase fixed monthly quantities of grains and other commodities at a highly-subsidized price from a government-run Fair Price Shop (FPS). In practice, the resulting

---

<sup>1</sup>For instance, the World Bank has a dedicated initiative—ID4D (Identification for Development)—to help countries “realize identification systems fit for the digital age.” (<https://id4d.worldbank.org/>).

dual-price system creates strong incentives for corrupt intermediaries to divert grains to the open market; the most recent nation-wide estimate is that 42% of grain was diverted as of 2011-12 (Drèze and Khera, 2015). Leakage can happen both through *identity* fraud, whereby FPS dealers collect grains against fake or inactive beneficiaries; and through *quantity* fraud, whereby they do not provide beneficiaries with their full legal entitlements.

Aiming to reduce leakage, the government reformed PDS implementation in two phases. In the first phase—which we refer to as “Aadhaar-based biometric authentication” or ABBA—it installed electronic Point-of-Sale (ePOS) machines in FPSs and required beneficiaries to obtain an Aadhaar number, link (or “seed”) it to their PDS account, and authenticate by scanning their fingerprints each time they transacted. ABBA generated a digital record of transactions for which beneficiaries had “signed” biometrically, in contrast with the status-quo of record keeping on paper. In the second phase, the government used these records to adjust downwards (or “reconcile”) the amounts of grain it disbursed to each FPS to reflect the undistributed stocks that the FPS should still have. The ABBA and reconciliation reforms were introduced sequentially, but were closely related because the former created the digital record used as the basis for the latter. Prior to the reform, the government did not have credible records of distribution from dealers to beneficiaries, and would therefore disburse the full amount of grain needed to satisfy the entitlements of all beneficiaries.

To evaluate these reforms, we worked with the government of the state of Jharkhand (GoJH) to randomize the order in which it introduced ABBA across 132 sub-districts in 10 districts. Our evaluation sample is representative by design of 15.1 million individuals in 3.3 million beneficiary households in 17 of Jharkhand’s 24 districts, and representative on observables of the rest. GoJH then launched reconciliation simultaneously in all areas two (eleven) months after deploying ePOS devices in control (treatment) areas. We therefore present experimental estimates of the impact of requiring ABBA to collect benefits, and quasi-experimental estimates of the impact of reconciliation using a pre-specified event study framework, a placebo group of PDS commodities not subject to reconciliation, and experimental variation in the duration of exposure to ABBA prior to reconciliation.

Our focal outcomes are the value of goods disbursed by the government, value received by beneficiaries, and the difference between these (i.e. leakage). We measure these using comprehensive administrative data on disbursements of commodities to all ration shops matched to original survey data on commodity receipts and transaction costs collected in four rounds (one baseline and three follow-up rounds) from a panel of 3,840 PDS beneficiaries. We use the first follow-up to study the effects of ABBA, and the remaining to study reconciliation.

GoJH implemented ABBA rapidly and complied closely with the experimental design. Six months after treatment onset, 95% of beneficiary households in treated areas had at

least one member with an Aadhaar number seeded to the PDS account, and 91% reported that transactions at their FPS were being authenticated, while only 6% of control households reported the same. ITT estimates can thus be reasonably interpreted as those of introducing ABBA in the period we study.

Leakage in the control group at the time of the first follow-up was 20% of the value disbursed. This was driven primarily by 15% of beneficiaries who did not receive any benefits in any given month. At most 3% of these were outright “ghosts;” the majority were real beneficiaries who reported being unable to collect their benefits (usually because they were told that there were no stocks of grain available).

ABBA by itself had small effects on average. It did not decrease (and if anything slightly increased) government spending, and did not substantially change mean value received by beneficiaries or mean leakage. We also find no meaningful changes in measures of the quality of goods received, market prices, or beneficiaries’ food security. Effects were not worse in areas with weaker connectivity, as some had feared.

However, beneficiaries did incur 17% higher flow transaction costs to collect their benefits (a Rs. 7 increase on a base of Rs. 41), due in part to a doubling in the number of unsuccessful trips to the FPS. ABBA also had substantial negative impacts for some people. The probability that a beneficiary received no commodities at all in a given month increased by an estimated 2.4 percentage points ( $p < 0.1$ ), implying that nearly 300,000 people lost access to benefits. Exclusion was concentrated among the 23% of households who had not “seeded” their ration cards at baseline, and especially among the 5% who had not done so even six months after baseline. The mean value of rice and wheat received fell by Rs. 49 and Rs. 223 (or 11% and 62%) in these groups, and their probability of not receiving *any* rations increased by 10 and 41 percentage points (a 50% and 158% increase) respectively. This pattern of incidence is likely to be regressive, as unseeded households tend to be less educated than their seeded peers. These results are consistent with the critique that ABBA per se caused at least some “pain without gain” (Drèze et al., 2017).

A potential counterargument is that ABBA was a first step towards the introduction of reconciliation. Prior to the introduction of ABBA, GoJH had no means of obtaining data it trusted on the offtake of grain *from* FPSs. Given this, GoJH used to ship grain supplies to dealers as if *all* eligible beneficiaries had collected their benefits (i.e. there was no reconciliation). The introduction of reconciliation is arguably when disbursements (and potentially leakage) should fall. Consistent with this, treated dealers reported 18% lower profits and a 72% lower expected future bribe price for FPS licenses, suggesting that they expected a considerable fall in future rents with the impending introduction of reconciliation.

In line with this, we find that the onset of reconciliation coincided with a sharp 19%

drop in value disbursed by the government in control areas. However, only 78% of this was a reduction in leakage, and the remaining 22% represented a drop in value received by beneficiaries. In treated areas, where reconciliation was introduced after longer exposure to ABBA, the effects are even more pronounced: a 37% drop in value disbursed, of which 66% was a reduction in leakage and the remaining 34% a drop in value received. On the extensive margin overall we estimate that an additional 1.7 million people did not receive PDS benefits in July 2017 (the first month of reconciliation).

Thus, while reconciliation did meaningfully reduce dealer rents, dealers were able to pass on a considerable amount of pain to beneficiaries. Beneficiaries also “signed” biometrically for more grain than they actually received, illustrating how better authentication per se need not prevent quantity fraud from (correctly-identified) recipients. Given all these issues, reconciliation proved widely unpopular among both dealers and beneficiaries, forcing GoJH to pause it after four months before reintroducing a modified version the following year.<sup>2</sup>

These results may partly reflect the way GoJH managed the transition to reconciliation. Specifically, it chose to hold dealers accountable not only for grain delivered after reconciliation began but also for undistributed grain for the several months *before* reconciliation began (for which ABBA-based records now existed). Since this effect is more pronounced in the treated group, which had longer exposure to ABBA, we use our experimental variation to predict how reconciliation’s effects would vary with opening balances, and in particular to predict impacts if GoJH had not held dealers responsible for *prior* undistributed stock (which may have been diverted or spoilt). We estimate that this approach might have reduced leakage meaningfully, without reducing value received by beneficiaries.

Overall, we find that (as implemented) ABBA and reconciliation caused considerable exclusion, leading to 1.5-2 million people losing access to their PDS benefits at some point during our study period—0.3 million due to ABBA and 1.2-1.7 million due to reconciliation. At the same time, our results also suggest that most of this exclusion was due less to structural issues with authenticated reconciliation per se, and more to the way the transition was managed. Exclusion due to ABBA was concentrated among those who had not seeded their ration cards as there was no effective manual override option. Our data suggest that this margin of exclusion is likely to be insignificant once all beneficiaries are seeded. Exclusion due to reconciliation would likely have been mitigated had the government chosen to forgive past leakage and introduce reconciliation on a “clean slate” basis.<sup>3</sup>

---

<sup>2</sup>Suspension of anti-corruption reforms due to political pressure has been a recurrent pattern in India. For instance, a similar pattern was seen in the Direct Benefit Transfer reform studied by Barnwal (2019) and the financial management reform studied by Banerjee et al. (2020).

<sup>3</sup>This supports the idea that reforms to reduce corruption may be politically easier if some amount of past corruption is forgiven. This idea has been discussed by practitioners (e.g. Devlin and Chaskel (2010))

Our first contribution is to provide experimental evidence that attempts to reduce leakage by tightening identification standards in welfare programs can cause substantial harm to genuine beneficiaries through the increased risk of exclusion errors. More broadly, we add to the global evidence base on how increasing transaction costs can affect the incidence of welfare benefits in a regressive way (Currie, 2004; Kleven and Kopczuk, 2011; Bhargava and Manoli, 2015; Finkelstein and Notowidigdo, 2019; Deshpande and Li, 2019).

Second, and more generally, our results highlight the importance of considering the possibility of unintended harm from anti-corruption programs, in addition to the direct fiscal costs and benefits. Scholars of bureaucratic corruption have often cautioned that controlling corruption may incur non-fiscal or “shadow” costs such as slower decision-making, the inability to use “soft information,” or simply organizational inattention to other priorities (Klitgaard, 1988; Wilson, 1989). Yet, there is limited experimental evidence of such unintended costs. Our results show that simply focusing on fiscal costs and benefits of rolling out the reform (e.g. costs of procuring ePOS machines, and benefits of reduced disbursements) would have missed the important indirect costs of exclusion.<sup>4</sup>

Third, our results highlight the importance of transition costs when implementing complex reforms. The comparison with our own prior work on biometric payments in rural welfare programs in Andhra Pradesh (AP) reported in Muralidharan et al. (2016) is illustrative. GoJH rolled out ABBA rapidly without allowing for override mechanisms in case of failed authentication, and rolled out reconciliation state-wide in a single month. In contrast, the Govt of AP rolled out biometric Smartcards gradually over *several years*, with ample provision for manual over-rides to ensure continued payments to those unable to authenticate. The AP approach allowed for a gradual reduction in leakage, but with no harm to beneficiaries, which made the Smartcard program much more popular. These examples are consistent with the literature arguing for gradualism to reduce adjustment costs of reforms.<sup>5</sup>

Finally, our results caution against simplistic characterizations of the effects of new technologies such as biometric authentication. The uniformly positive results on biometric payments we report in our prior work in AP (where the reform reduced leakage *and* improved the beneficiary experience), may have contributed to a sanguine view of such reforms. The contrasting results reported in this paper highlight that impacts of a similar technology may vary sharply depending on the details of the program, intervention design, and implementation (Duflo, 2017). We discuss implications for both research and policy in the Conclusion.

---

but mostly ignored in the political economy literature (with one exception being David (2010)).

<sup>4</sup>In related work, Lichand and Fernandes (2019) find that the threat of audits reduced corruption but also displaced public health spending in Brazilian municipalities, leading to worse public health outcomes.

<sup>5</sup>This idea appears in many strands of the economics literature including investments under uncertainty (Dixit and Pindyck, 2012) and structural economic reforms (Wei, 1997).

## 2 Context and intervention

The Public Distribution System (PDS) is the main program by which the Government of India aims to provide food security to the poor. Through a network of over 527,000 ration shops known as “Fair Price Shops” (FPS), it delivers highly-subsidized wheat and rice to targeted households on a monthly basis, and other commodities such as sugar, salt, and kerosene on an occasional basis. Individual states administer targeting and distribution within their boundaries. The PDS (in all states) is implemented in two steps. The state government first disburses commodities to FPSs each month based on the number of registered beneficiaries, and FPSs then distribute these commodities to beneficiaries. Eligible households across India are entitled to 5kg/month of grain per member of the household. Rice and wheat are provided at a price of Rs. 3/kg and Rs. 2/kg through the FPSs, which is a 80-90% subsidy relative to market prices. Overall, the PDS costs roughly 1% of GDP to operate.

In part because it creates a dual-price system, distributing commodities at prices well below their market prices, the PDS has historically suffered from high levels of corruption: Drèze and Khera (2015) estimate that 42% of foodgrains nationwide and 44% in Jharkhand were diverted in 2011-2012, which is itself an improvement on the estimate of 73% by the Planning Commission in 2003 (Planning Commission, 2005). Leakage and corruption can take place both through “identity fraud” and “quantity fraud”. Under the former, beneficiary lists could include ineligible or inactive beneficiaries, and dealers and intermediaries could simply pocket the commodities disbursed against these names (and divert them to the open market). Under the latter, dealers could distribute a smaller quantity than the legal entitlement, adulterate commodities, or charge more than beneficiaries are supposed to pay.

To help address these issues, the Government of India has introduced several reforms including the use of electronic point-of-sale (ePOS) devices to process and record transactions between dealers and beneficiaries and enable reconciliation of shipments to dealers. ePOS devices perform biometric authentication using Aadhaar, India’s landmark unique ID system. As of June 2019, the Govt. of India had issued Aadhaar numbers to 1.24B people, or 91% of the country’s population, and had integrated it into several welfare programs, including the PDS.<sup>6</sup> Several officials and leaders have hailed Aadhaar as an enabler for wide-ranging governance reforms, with a former Finance Minister of India referring to Aadhaar as “a game changer for governance” (Harris, 2013).

However, government claims regarding the fiscal savings achieved by introducing Aadhaar have at times been met with skepticism, in part because they did not differentiate between

---

<sup>6</sup>Abraham et al. (2017) estimate that Aadhaar was being employed in at least 558 use cases as of 2017.

real reductions in leakage and increased exclusion of legitimate beneficiaries (Khera, 2016). In an important study, Barnwal (2019) uses difference-in-differences to show that delivering petroleum subsidies to Aadhaar-linked bank accounts led to a substantial reduction in government expenditure. However, the absence of matched household survey data makes it difficult to rule out the possibility that there was also some increase in exclusion. Surveys of PDS beneficiaries, meanwhile, have found some cases of exclusion that respondents attributed to Aadhaar, although the majority of exclusion was attributed to other issues (Abraham et al., 2018). There has been no experimental evidence to date on the impacts of an Aadhaar deployment in a welfare program, and also no well-identified study with *matched* administrative and household data on disbursements and receipts.

We study the effects of introducing Aadhaar in the PDS in the state of Jharkhand. Jharkhand is a relatively challenging environment in which to roll out such an ambitious reform. On state capacity, it ranked 17th out of 19 major states on the most recent Governance Performance Index (Mundle et al., 2012). As one concrete example of low state capacity, it had the highest rate of teacher absence among *all* Indian states in both 2003 and 2010 (Muralidharan et al., 2017).<sup>7</sup>

## 2.1 Aadhaar-based biometric authentication (ABBA)

Prior to the reforms, authentication in the Jharkhand PDS was relatively informal. Each beneficiary was assigned to a unique FPS and issued a ration card listing members of the household and displaying a photograph of the household head. To collect benefits, any one of these listed household members was expected to appear in person with the ration card at the assigned FPS. Anecdotally, it was not uncommon for neighbors or friends to collect benefits on their behalf, or for dealers to hold on to beneficiaries' ration cards themselves. Dealers were expected to record transactions both on ration cards and in their own ledgers, but these records were typically not audited (see Figure 1, Panel (a)).

In August 2016, as part of a nationwide rollout, GoJH started requiring beneficiaries to conduct Aadhaar-based biometric authentication (ABBA) when they came to collect their rations (Figure 1, Panel (b)). ABBA required beneficiaries to have “seeded” (linked) their ration cards with their Aadhaar numbers,<sup>8</sup> and to authenticate themselves via an ePOS

---

<sup>7</sup>Jharkhand also ranked low among states on rural teledensity (40 telephone or mobile phone connections per 100 people in rural Jharkhand as of 31 October 2017, 19th out of 19 major states) and in the middle for Aadhaar penetration (93% penetration as of 31 December 2017, 17th out of all 36 states).

<sup>8</sup>To seed their ration card, a household first needed to have at least one of the members listed on the ration card obtain an Aadhaar number, either at camps organized specially for this purpose or subsequently by applying at the local block or district office. It then needed to link this Aadhaar number to its ration card, again either at camps organized for this purpose or by applying at the block or district office. FPS dealers were not involved in the seeding process and could not seed households at the FPS.

device at the FPSs, configured to operate in one of three modes, depending on connectivity: online (81% of shops), offline (15%), and partially online (4%).<sup>9</sup>

GoJH launched ABBA after Aadhaar-seeding rates exceeded 75% and aimed to complete the process of seeding Aadhaar numbers to ration cards shortly thereafter. As of May 2016 (three months prior to ABBA launch), 76.5% of ration cards in areas assigned to treatment and 79.9% of those in areas assigned to control had been seeded with at least one Aadhaar number. These figures had risen to 94.5% and 92.6% by October of 2016 (three months prior to the reference period in our endline survey) and to 99.8% and 99.5% by May of 2018 (roughly one year after the period we examine experimentally).

The main value of ABBA to GoJH was that it enabled digital record-keeping that was transmitted to a central server from the ePOS devices. After authentication, the device would display any previously uncollected commodity balances to which the beneficiary was entitled, including the current month’s entitlement and any uncollected balance from the previous month. Unclaimed entitlements from two or more prior months would lapse. After completing a transaction the dealer would record the amount of each commodity purchased in the device. The government accessed this data in real time in the case of online devices, and dealers were expected to upload and synchronize data within 48 hours of a transaction in the case of partially online and offline devices.

## 2.2 Reconciliation

Prior to the introduction of ABBA using ePOS devices, the monthly disbursement of commodities to FPS by GoJH was set at the full amount needed to meet the entitlements of all registered beneficiaries (regardless of whether they were actively collecting PDS benefits). We see this policy borne out in administrative data: prior to reconciliation, disbursements exactly matched entitlements (see Figure E.1, Panel (b)). This reflected in part the simple fact that the government had no timely and reliable data on transactions at the shops.

The ABBA rollout was intended among other things to provide a source of such data, and to enable the second component of the reform, when shipments of grains to FPSs started

---

<sup>9</sup>In *online mode*, the device required the operator to input a ration card number. It then displayed a list of all individuals who were both (i) listed as beneficiaries on the relevant ration card, and (ii) had an Aadhaar number linked (“seeded”) to the card. The dealer selected the individual present, and the device then prompted him/her to place a finger of choice on the device’s scanner to be authenticated against the central Aadhaar database. In *offline mode*, the device captured and stored fingerprint and transaction information, to upload later from a location with connectivity, but did not perform real-time authentication checks. In *partially online mode*, the device functioned in online mode if it detected a network connection and in offline mode otherwise. Dealers did not have discretion to select modes. Our experimental design (below) randomized receipt of a device but not device mode, so that reported treatment effects are an average of mode-specific effects given the assignment policy.

getting reduced to account for undistributed grain stocks with the FPS. We refer to this second component as “reconciliation.” Strictly speaking, ABBA was not a prerequisite for reconciliation. The government could have, in principle, introduced reconciliation based on verification of paper records. However, in practice, given limited staffing and state capacity for physical audits of paper records, the digital records enabled by ABBA were de facto a prerequisite for reconciliation at scale.

By June of 2017, ePOS devices were in active use in 93% of FPSs in our study area, including those in control blocks, where they were rolled out during April and May. Starting in July, GoJH began reconciling its disbursements of rice and wheat, though not of sugar, salt or kerosene (Figure 1, Panel (c)). The full formula used to determine disbursements under this regime is in Appendix E. To summarize, the government’s new policy was to calculate (a) the amount each dealer would need to meet claims by beneficiaries against the current month’s entitlements, as well as any outstanding claims on the preceding one month’s entitlements, and (b) the amount the dealer should have in stock given the full history of deliveries and transactions, and then disburse the difference between these quantities.

While GoJH introduced reconciliation at the same time in both treatment and control blocks, treated blocks had been using ePOS devices for substantially longer than control blocks. As a result, as per the digital ABBA records, they accumulated larger balances of grain for which GoJH could hold them accountable. Combined with the fact that GoJH held dealers responsible for *all* past undisbursed grain as per ABBA records, reconciliation may have had differential effects across blocks’ treatment status. Moreover, to the extent dealers anticipated this, we should interpret the experimentally estimated effect of early receipt of an ePOS device as potentially including the effect of the anticipation that transactions recorded using that device would be subject to future reconciliation. In other words, while reconciliation itself was not randomized, the *reconcilability* of transactions was. We return to these issues in interpreting the results below.

### **2.3 Anticipating and interpreting impacts**

To help interpret our results, we describe a simple conceptual framework to clarify whether and under what conditions reforms such as this may be effective. Appendix C provides a more formal treatment.

Consider the generic problem of transferring value from a principal to a beneficiary via an agent. Authenticated reconciliation could reduce two forms of leakage. The first is leakage from transfers sent to people who do not actually want them—either real households that do not demand grain at the subsidized price, including for example those that have

migrated away, or “ghost” households that do not exist at all (identity fraud as noted above). In the status quo the agent can simply pocket these transfers. Authentication by itself—without reconciliation—does not prevent the agent from pocketing these transfers, and hence likely has limited impact on leakage. Authenticated reconciliation prevents this: since the beneficiaries in question do not show up to authenticate, disbursements that were meant to fulfil their entitlements cease.

The second mechanism is more subtle and involves bargaining between agents and the beneficiaries who *do* want their transfers over how to divide them (quantity fraud). This bargaining takes place in the context of local power structures that shape the results – for example, how effectively beneficiaries can complain to local government if they are mistreated. After the reform bargaining becomes more complex, as the parties must agree not just on a division of the transfer but also on what message to send the government about this division via the records they jointly authenticate and submit. This message matters because it determines how much grain they receive to divide in the future. Putting this new consideration “on the table” could shift the bargaining equilibrium in either party’s favor. If in the beneficiary’s favor, this reduces leakage. For instance, the beneficiary might refuse to sign for an amount greater than they received, boosting their bargaining power.

Both mechanisms also imply risk of increased exclusion. In the first, agents who lose rents they had formerly skimmed from transfers to beneficiaries that did not demand them might seek to recoup some of their losses by extracting more rent from the beneficiaries that do. Such displacement of corruption (as seen for example in Yang (2008) and Fisman and Wei (2004)) creates a trade-off between errors of inclusion and exclusion. Under the second, shifts in bargaining power could favor either the beneficiary (in which case exclusion may fall) or the agent (in which case it may rise).

In addition to these risks and potential rewards which are intrinsic to authenticated reconciliation, the specific way in which the transition was managed in Jharkhand created additional risks. Since there was limited provision for manual overrides in cases of beneficiaries being unable to authenticate,<sup>10</sup> ABBA had the potential to mechanically exclude beneficiaries who had not seeded an Aadhaar number to their account by the time ePOS devices rolled out. Further, since reconciliation aimed to hold PDS dealers responsible not just for future receipts but also for *prior* undistributed stocks of grain (that they may have already diverted), dealers might see sharp initial drops in grain received (at the onset of reconciliation) and choose to pass some of this pain through to beneficiaries. Given this, our

---

<sup>10</sup>If authentication failed on three consecutive attempts, the beneficiary could opt to receive a one-time password texted to their mobile phone number as a fallback method of authentication. However, this option may not have been feasible for those without mobile phones.

empirical analysis will aim both to estimate the overall impacts of ABBA and reconciliation, and also to understand to what extent these reflect the design choices made in transitioning to the new system.

### 3 Research design

The design follows a pair of pre-specified and pre-registered analysis plans, one for ABBA and one for reconciliation.<sup>11</sup> We filed the former on 14 April 2017 before receiving data from the first endline survey; we filed the latter on 26 April 2018 before receiving administrative data on disbursements and before analyzing data from subsequent endline surveys. Appendix B contains results from any analysis pre-specified in these plans that we do not discuss in the paper, and also lists all analyses in the main text that are additional to those pre-specified. Below we summarize randomization, sampling, and data collection methods, with further details in Appendix D and full details in the pre-analysis plans.

#### 3.1 Randomization

To obtain policy-relevant estimates of impact, we sought to design an evaluation that was “at scale” in each of the three senses identified by Muralidharan and Niehaus (2017). These include conducting our study in a sample that is representative of the (larger) population of interest, studying the effects of implementation at large scale, and having large units of randomization to capture general equilibrium or other spillover effects such as changes in the market prices of subsidized commodities.

We first sampled study districts. Of Jharkhand’s 24 districts, we excluded 1 in which the intervention rollout had already begun and 6 in which a related reform (of Direct Benefit Transfers for kerosene) was being rolled out.<sup>12</sup> From the remaining 17 districts, home to 24 million people and 15.1 million PDS beneficiaries, we randomly sampled 10 districts within which to randomize the rollout of the intervention. This design ensures representativeness of the 17 districts in our frame. In practice, our 10 study districts appear fairly comparable on major demographic and socio-economic indicators to all the 14 remaining districts of Jharkhand (Table A.1). Our frame is thus arguably representative of the full population of 5.6 million PDS households and 26 million PDS beneficiaries in the state.

Second, we assigned treatment to large units. We randomized the rollout at the level of

---

<sup>11</sup><https://www.socialscienceregistry.org/versions/39275/docs/version/document> and <https://www.socialscienceregistry.org/versions/39274/docs/version/document> respectively.

<sup>12</sup>The intervention had already started in the capital Ranchi district at least three months prior to our experiment, allowing for any initial glitches in implementation to be resolved.

the sub-district (“block”), which on average covers 73 FPSs and 96,000 people. Figure A.1 maps treated and control blocks and illustrates their geographic balance and coverage of the state. We allocated 132 blocks into a treatment arm of 87 blocks and a control arm of 45 blocks, reflecting the government’s preference to delay treatment in as few blocks as possible. Treatment and control blocks are similar in terms of demographic and program characteristics, as one would expect (Table 1, Panel A). Of 12 characteristics we examine, one is marginally significant at the 10% level.

Finally, the evaluation was conducted within the context of a full-scale rollout, as GoJH deployed ePOS devices to 36,000 ration shops covering the entire population of 26 million PDS beneficiaries in the state. This deployment involved a major effort by the government and was the stated top priority of the Department of Food and Civil Supplies for the year and (anecdotally) the single largest use to which they put staff time. We thus measure the effects of implementation at full scale by a bureaucratic machinery fully committed to the reform, which are the effects of interest for policy purposes.

Consistent with this commitment, we find that GoJH complied closely and quickly with the treatment assignment (Figure A.6 provides the timeline of the intervention rollout in treated and control blocks). By the time of our follow-up survey, households in treated blocks reported that 96% of dealers in treated blocks possessed an ePOS device and 91% were using it to process transactions (Table 1, Panel C). ePOS utilization was stable at 90-91% in treated blocks during January-March 2017, which increases our confidence that we are estimating steady state impacts and not transitional dynamics. In control blocks, on the other hand, 5% of dealers possessed a device and 6% were using it to process transactions, largely reflecting early rollout in one control block.<sup>13</sup> Overall these figures suggest that it is sensible to estimate intent-to-treat effects and to interpret them as fairly close approximations of the overall average treatment effect.

## 3.2 Sampling and Data Collection

Our data collection focused on measuring the value of commodities disbursed by the government and the value received by beneficiaries (net of price paid), as well as the real transaction costs incurred by dealers and beneficiaries to distribute and collect these benefits. Leakage is the difference between value disbursed and value received.

To measure these quantities, we begin with administrative records. We obtained information on monthly quantities of commodities disbursed to all FPSs from the National Informatics Centre (NIC), and the administrative database of eligible PDS beneficiaries and

---

<sup>13</sup>Of the 31 control households that report a dealer using an ePOS device, 24 are in one block. The remaining 7 are scattered across 6 other blocks and most likely reflect reporting errors.

their assignment to FPSs from GoJH. We used the latter to draw samples of dealers and households to survey, and attempted to survey them four times – once at baseline and then at three subsequent follow-ups. We selected 3 FPSs via PPS sampling in each study block, for a total of 396 shops. We successfully interviewed the dealers operating 367 (93%) of these shops at baseline, and 373 (94%) of them in the endline. Dealer surveys covered measures of the quantity of commodities received by the shop each month, their operating costs, the dealers’ perceived value of FPS licenses and interest in continuing to operate a ration shop, and stated preferences for the reform as opposed to the status quo system. Enumerators also measured using our own equipment the strength of the four major cellular networks at the shop in order to capture connectivity.<sup>14</sup>

For each sampled ration shop we sampled 10 households from the government’s list of PDS beneficiaries, which had been created as part of a targeting exercise conducted in 2015 to comply with the National Food Security Act of 2013. This generated a target sample of 3,960 households. We attempted to interview these households for baseline and three follow-up surveys to create a household-level panel. We ultimately identified and interviewed the corresponding household at least once in 97% of cases.

We timed follow-up surveys and their associated recall periods to obtain continuous monthly data on beneficiaries’ experiences with PDS from January through November of 2017. Figure A.6 illustrates the recall window covered by each survey. We use data from follow-up 1, covering January through March, to measure the impacts of ABBA, and use data from all three follow-ups to examine the impacts of reconciliation. Topical coverage varied across surveys; follow-up 1 was most comprehensive, while follow-ups 2 and 3 measured a subset of outcomes (e.g. for households, the quantities of each commodity received). In particular, we did not measure market prices in follow-ups 2 and 3 and so do not examine price effects of reconciliation.

Survey and item response rates are well-balanced overall. Table A.3 reports survey response rates by arm; in general these are well-balanced, and in particular we obtained responses from 97% of households in both arms to at least one survey, and from 90% of households in both arms at Endline 1. As the regression-adjusted difference at Endline 1 is nevertheless marginally significant ( $p = 0.09$ ), we also check in Table A.4 for differences in

---

<sup>14</sup>In follow-up surveys, we expanded the number of dealers surveyed, as a few (7.9%) of our sampled households had been re-assigned to new dealers in the normal course of operations during the 10 months since baseline. We report results for both the original and augmented dealer samples, as the reassignment rate of households is balanced across treatment and control, and the incremental dealers are not statistically distinguishable from the original ones on measured characteristics (Table A.2). Note that the reassignment of households to other shops does not affect our ITT estimates because we track the originally sampled households and because their reassignment was to other FPS in the same block, with the same treatment status.

the composition of attrition at Endline 1, and find no strong patterns. Finally, Table A.5 reports non-response rates among those households we did survey to specific questions used to calculate our main outcomes, and finds no significant differences.

We randomized blocks into treatment and control groups using administrative data before our baseline survey was completed, and report balance on these metrics in Table 1 - Panel A. In Panel B, we also report key outcomes based on the baseline household surveys including the amount and value of commodities received, and see that these are also balanced across treatment and control groups.

### 3.3 Estimation strategy: Aadhaar-based biometric authentication

To examine the impacts of ABBA we estimate intent-to-treat specifications of the form

$$Y_{hfb_s}^t = \alpha + \beta Treated_{bs} + \gamma Y_{hfb_s}^0 + \delta_s + \epsilon_{hfb_s}^t \quad (1)$$

where  $Y$  is an outcome measured in month  $t$  for household  $h$  assigned to FPS  $f$  in block  $b$  of stratum  $s$ .<sup>15</sup> Regressors include an indicator  $Treated_{bs}$  for whether that block was assigned to treatment, the baseline value  $Y_{hfb_s}^0$  of the dependent variable, and a stratum fixed effect  $\delta_s$ . Where we observe baseline values for multiple months we take their average. Where the baseline value is missing we set it equal to the overall mean value, and include an indicator for baseline missingness.<sup>16</sup> When using survey data we weight specifications by (inverse) sampling probabilities to obtain results that are representative of the sample frame.<sup>17</sup> We use analogous specifications for outcomes measured at the level of the FPS or block. We pool observations for January-March 2017, following our pre-specified plan for dealing with the possibility of non-stationary treatment effects.<sup>18</sup>

We impute zeros when calculating quantities and value received for verified “ghost” ration cards (which account for 1.6% of sampled households and do not differ by treatment and control groups). We report standard errors clustered by block. We report  $p$ -values for well-

---

<sup>15</sup>Because the randomization algorithm created 6 strata (3 urban and 3 rural) of size 1, we create a single fixed effect  $\delta_s$  for each of these two groups.

<sup>16</sup>This approach yields consistent estimates given that  $Treated_{bs}$  is experimentally assigned, so that the issues Abrevaya and Donald (2017) demonstrate when the regressor of interest is correlated with the partially observed covariates do not arise.

<sup>17</sup>Unweighted estimates are substantively the same but more precise.

<sup>18</sup>We pre-specified that we would (i) estimate models for each month individually, pooled models, and pooled models with a linear interaction between treatment and month, and then (ii) choose which specification to privilege based on the overall tendency of the trend terms to be significant predictors of primary outcomes. We generally do not observe evidence of trends, consistent with the fact that program implementation also appeared to have stabilized, and therefore privilege the pooled estimators. Time-varying estimates are in Appendix B.

defined summary measures of outcomes such as value disbursed, and for outcomes at the individual commodity level also report  $q$ -values adjusted to control the false discovery rate.

### 3.4 Estimation strategy: reconciliation

GoJH introduced reconciliation in July 2017 across both treatment and control groups simultaneously, and suspended it in November 2017. After observing this sequence of events, but before analyzing any data covering this period, we specified the following model to capture reconciliation’s impacts:

$$Y_{hfbst} = \alpha_{hfbst} + \gamma t + \beta_R R_t + \beta_{Rt} R_t(t - t^*) + \eta P_t + \delta_s + \epsilon_{hfbst} \quad (2)$$

where  $R_t$  is an indicator equal to one if disbursements for month  $t$  were calculated using the reconciliation formula (i.e. for July through October),  $t^*$  is the first month of reconciliation (i.e. July), and  $P_t$  is an indicator for the one post-reconciliation month in our data (i.e. November). We estimate the model separately for treated and control blocks; to compare the two, we pool the data and interact all regressors with an indicator for treatment. We report standard errors clustered by FPS.<sup>19</sup> We report results for both reconciled commodities (rice and wheat), and unreconciled ones (salt, sugar, and kerosene), with the latter providing a plausible placebo group.

This specification embodies several substantive assumptions. First, we assume the effect of reconciliation is identified once we control for a linear pre-trend. This is a strong assumption, but the best that is realistic with 6 months of pre-treatment data, and as it turns out yields an excellent fit. Second, by including an indicator for November we do not impose that outcomes revert immediately to what they would have been absent the intervention. Doing so would significantly improve power if true, but seems implausible. Third, we model the potential for (linear) time variation in the treatment effect. This reduces power and increases the risk of overfitting if the treatment effect is in fact time-invariant, but seems appropriate given that theory suggests reconciliation should generate transitional dynamics.

---

<sup>19</sup>This is as specified in our pre-analysis plan, and differs from the experimental results where we cluster at the block-level as the identifying variation in that case is at the block level. In Table 8, where we do use block-level randomization as an instrument, inference is substantively the same if we cluster at the block level.

## 4 Results: Aadhaar-based biometric authentication

### 4.1 Value transfer

We measure value ( $V$ ) as the sum across commodities  $c$  of quantity  $Q$  multiplied by the difference between the district-specific market price ( $p_d^m$ ) of that commodity, which we define as the median price reported at follow-up 1 by households in control blocks of that district, and the statutory ration shop price ( $p^s$ ). Formally,

$$V_{ht} = \sum_c Q_{cht}(p_d^m - p^s) \quad (3)$$

Entitlements are meaningful: their mean value evaluated using Equation 3 is Rs. 595 per month, 14% of the national rural poverty line for the average household in our sample.<sup>20</sup>

We first examine leakage in the control group to better understand the counterfactual (Table 2). The government recorded disbursing commodities worth approximately the full entitlement amount: an average of Rs. 579 per month, or 98% of mean value entitled. Beneficiaries received Rs. 463 on average, which is less than their entitlement and implies that roughly 20% by value of the commodities the government disbursed did not reach them. Of this 20%, fairly little is attributable to outright “ghost” beneficiaries.<sup>21</sup>

Recall from Section 2.3 that authenticated reconciliation is most likely to be helpful in reducing leakage from transfers to households that do not demand them, either because they are ghosts or perhaps because they are well off enough that they do not wish to purchase inferior goods at a subsidized price. In our data the bulk of the leakage occurs on the extensive margin, i.e. is attributable to the 15% of households who do not collect benefits in any given month (Figure 2), perhaps indicating that they do not demand them. However, few of these are ghosts: we located and interviewed 97% of sampled households, confirmed that 1.5% were ghosts, and cannot be sure of the status of the other 1.5% (Figure A.2).<sup>22</sup> A key question is thus whether the other 12-14% of households that never collected their transfers actually wanted them.

---

<sup>20</sup>Ration limits depend on the size of the household and category of ration card it holds. An average household in our sample had 4.4 members, and the national rural expenditure poverty line was Rs. 972 / person / month (Planning Commission, 2014).

<sup>21</sup>Control means present averages across all months of data in the first follow-up survey (January to March 2017). We expect beneficiaries generally have a fairly accurate assessment of the quantity of grain they receive. Anecdotally, most FPSs had digital weighing scales which would be difficult to tamper with; some used mechanical scales in which case beneficiaries knew that the counterweights weighed less than they should but did not object as the differences were small. This is consistent with the finding reported below that *conditional* on obtaining any benefits, households report obtaining ~94% of their entitlements.

<sup>22</sup>We classify a household as a ghost if (i) the survey team cannot locate it after at least two attempts, and (ii) two neighbors warrant that no such household exists. Details are in Appendix D.

It seems that most of them did. When we asked these households *why* they never collected, only 1% (0.12% of all households) said that they did not try to because they did not need their ration; the rest either did try or did not because they did not think they would succeed. Meanwhile the households that did receive at least some benefits collected 94% of their transfers on average. Overall, then, it seems that most ration cards belong to real households that demand their transfers, but that leakage and exclusion are mainly on the extensive margin: most get their transfers, but a sizeable minority do not.

#### 4.1.1 Value disbursed

Table 2 summarizes impacts of ABBA on value transfer during January-March 2017, beginning in Panel A with value disbursed by the government. We observe this outcome for the universe of FPSs in our study area (8,924 shops) and therefore use all of these data, with outcomes expressed per ration card  $\times$  month. We expect no meaningful changes to disbursements, as the government’s policy during this period was to disburse to each FPS in each month the full amount to which households assigned to that shop were entitled. We find this is largely the case, though we do find some modest substitution away from wheat and towards rice which nets out to a small but statistically significant increase in total value disbursed of Rs. 12 per ration-card month, or around 2%.<sup>23</sup> In any case, there is no evidence that ABBA by itself saved the government money.

#### 4.1.2 Value received

Panel B reports effects on value received by households using survey data. We see some directional evidence of the shift from wheat to rice noted above, but no significant change in overall value received. A 95% confidence interval for this effect is Rs.  $[-25.2, 22.8]$ , ruling out decreases greater than 4.3% and increases greater than 3.9% of value disbursed. Any effects on value received by the average household were thus small in economic terms.

In the appendix we also examine impacts on several other margins that might qualify this result, but do not find significant effects. We see no significant changes in the mean quantity of any commodity received (Table A.6, Panel B) and (unsurprisingly) no significant changes in the market prices household report facing, with the possible exception of a fall in the price of sugar (Table A.7, Panel A). Respondents in the control group generally do

---

<sup>23</sup>By default the government provided rice to rural blocks, but prior to the reform it made exceptions for those that expressed a desire for wheat, providing them with rice and wheat in 3:2 proportions. After the reform it appears to have reduced such exceptions. It is also possible that dealers lobbied for a slightly more generous accounting of their beneficiary lists in response to the reform, which they opposed. The increase in total value disbursed is due to the increase in total quality of grain disbursed, not due to substitution towards more expensive grains, as both wheat and rice have a mean market price of around Rs. 20 / kg.

not report often receiving adulterated or low-quality goods, and we generally do not find significant treatment effects on these outcomes (Table A.8). We also find no significant changes in respondents' stated willingness to accept (WTA) in lieu of the bundle of goods they actually purchased at the FPS in each month, a metric which should capture both quantity and quality as perceived by beneficiaries. We can rule out effects on WTA outside of  $[-5.5\%, 3.6\%]$  at the 95% level.<sup>24</sup> Finally, we see no significant effects on two standard measures of food security, with 95% confidence intervals expressed in control group standard deviations of  $[-0.11\sigma, 0.12\sigma]$  and  $[-0.11\sigma, 0.09\sigma]$  respectively (Table A.9).<sup>25</sup>

### 4.1.3 Leakage

Given that value disbursed increased slightly while value received was unchanged, we do not expect to find reductions in leakage. Panel C of Table 2 tests this directly. We use a Seemingly Unrelated Regressions framework with the ration card  $\times$  month as the unit of analysis and with (i) value received as reported by the household, and (ii) value per ration card disbursed to the corresponding block as the dependent variables, and then report the difference between the estimated treatment effects on these variables. We estimate that leakage increased insignificantly by Rs. 14 per ration card  $\times$  month. We can reject large decreases in leakage as a share of value disbursed, with a 95% confidence interval equal to  $[-1.7\%, 6.6\%]$ .

The figures in Table 2 pick up leakage on the quantity margin (e.g. the diversion of food grains) but may not pick up leakage due to overcharging by the FPS dealer. We examine overcharging separately in Panel D of Table A.7. The average control group household overpaid by Rs. 8 for the bundle of commodities it purchased, representing a small share (less than 2%) of total value received. Treatment reduced overcharging by a statistically insignificant Rs. 2.6. This makes sense as the intervention did not directly change marginal (dis)incentives for over-charging.

Overall, ABBA per se had no discernable impact on leakage. This is consistent with the fact that (prior to reconciliation) the government continued to disburse a fully monthly allotment of grain to each ration shop. Leakage could thus fall only if dealers responded to ABBA by passing on more of this grain to beneficiaries, which they do not appear to have done.

---

<sup>24</sup>A caveat is that this question appeared to confuse a number of respondents, as 48% gave at least one inconsistent answer to our series of binary choice WTA questions.

<sup>25</sup>Any treatment effects through indirect impacts on access to other, non-PDS benefits which also required Aadhaar are likely to be minimal since the difference in Aadhaar registration rates between treatment (96%) and control (92%) was only 4%.

## 4.2 Transaction costs

Using household survey data, we estimate that the average control group household spent the monetary equivalent of Rs. 41, or 9% of mean value received, in order to collect its benefits in March 2017. We calculate this using information on the individual trips they took to the ration shop, whether each trip succeeded, the time each trip took, and any money costs incurred (e.g. bus fare), as well as information on the opportunity cost of time of the household member who made the trip. Treatment increased these transaction costs by a small but significant amount: Rs. 7, or around 1.5% of value received and 17% of the control mean (Table 3, Column 1).<sup>26</sup>

Using dealer survey data, we reject economically meaningful treatment effects on dealer costs of storing and transporting grains (Table 3, Columns 2-3), which is what we would expect given the lack of an impact on quantities. Finally, using official data and budgetary records, we calculate that the cost of ePOS deployment was Rs. 6.2 per ration card per month, which was a 5% increase on GoJH’s base cost of Rs.144 per ration card per month operating the PDS.<sup>27</sup> Thus, overall transaction costs across the government, dealers, and beneficiaries increased by Rs. 13.6 per ration card per month, which represents a non-trivial 7.8% increase on a base of Rs. 175.

## 4.3 Distributional and heterogeneous effects

While the estimated average effects on beneficiaries are not significantly different from zero, this does not directly address the main risk of stricter identification requirements, which is that a subgroup of beneficiaries is unable to meet these and loses access to their benefits entirely. The distributional effects of treatment suggest this was the case. Figure 2 plots the CDFs of value received in the treatment and control groups separately; these track each other closely except for values close to zero, where there is more mass in the treatment group. The probability that a treated household received zero value is 2.4 percentage points higher

---

<sup>26</sup>In Table A.10 we examine impacts on the variables that feed into our total cost measure; the cost increase appears to be due to (i) a significant increase in the number of trips that were unsuccessful in the sense that they did not result in any purchases, which doubled from 0.13 per household per month to 0.26, and (ii) an increase in the opportunity cost of time of the household member who collected benefits. The latter likely reflects the fact that on average only 2.3 household members (out of 5.1 listed on the ration card) had seeded an Aadhaar number to the ration card and were thus able to authenticate transactions. The reform thus reduced households’ flexibility to send whoever could be spared from other work.

<sup>27</sup>The government paid around Rs. 1,600 per month per ePOS machine to an IT provider inclusive of equipment rental, maintenance, and training. The average FPS in our data has 257 households, yielding an incremental cost of Rs. 6.2 per ration card per month. While it is possible that some administrative costs associated with paper-based record keeping were reduced (including time taken to do so), these savings were not reported in any official spending records. Thus, we treat the costs of ePOS deployment as the change in administrative cost in treatment areas.

than a control household (Table 4, Column 1), significant at the 10% level.

For a sharper test, we examine how impacts differed for the 23% of households that were “unseeded” at baseline, meaning that no member’s Aadhaar number had been linked to their ration card. These households were at greatest risk of losing their benefits.<sup>28</sup>

Losses are indeed concentrated among unseeded households (Table 5). The reform lowered value received by this group by Rs. 49 per month, equivalent to 12.6% of their control group mean and significantly different both from zero and from the mean effect among seeded households. On the extensive margin, treatment lowered the probability that unseeded households received any benefit by 10 percentage points, also significantly higher than the (insignificant) impact on seeded ones. While the experiment does not identify specific households that counterfactually would not have been excluded, this decrease fully accounts for the overall decrease in the share of households receiving any benefits. Treatment effects on stated willingness to accept are also significantly lower for unseeded households, though not significantly different from zero. Transaction costs, on the other hand, increase slightly more for seeded households, consistent with the idea that they are able to continue transacting with the system, albeit at a higher cost.

Further evidence that exclusion was concentrated among unseeded beneficiaries is seen by looking at heterogeneity as a function of Aadhaar seeding status in October 2016 (at which point, 94.5% and 92.6% of households in treatment and control groups were seeded). With the caveat that this is after the baseline and experimental rollout of ABBA, it is still a few months before the Jan-March 2017 reference period of our follow up survey, and hence illustrative. We see that losses are concentrated completely in the small group of households who were still unseeded as of October 2016. The mean value of benefits received fell by Rs. 241, or 62% of the control mean; and the likelihood of receiving no benefits increased by 41 percentage points, 158% higher than the control mean (columns 4-6). Unseeded households were less educated on average, and also more likely to belong to (disadvantaged) scheduled tribes suggesting that the exclusion was regressive (Table A.17).

Overall, the results suggest that the reform did cause a significant reduction in value received for the households least prepared for the reform, driven by the total loss of benefits of a subset of these households. These effects are not obvious in the overall averages in Table 2 (since unseeded households were a minority), yet they impacted a large number of people. Multiplying the 2.4 percentage point increase in the likelihood that a household in a treated block received no benefits (Table 4, Column 1) by the total number of PDS beneficiaries in treated blocks (6.25 million), we estimate that around 150,000 beneficiaries were likely

---

<sup>28</sup>The administrative records are missing data on baseline seeded status for 12% of households, which we omit from this analysis. Missingness is not associated with assignment to treatment.

denied benefits in treated blocks alone. If we extrapolate to include the 7 non-study districts (that our study sample was representative of, and which rolled out ePOS everywhere) in addition to treated study blocks, we estimate that 296,000 beneficiaries were denied benefits due to ABBA alone.<sup>29</sup> However, one positive implication of exclusion being concentrated among those who were unseeded is that it is likely that the exclusion we document was a transitory phenomenon, which would reduce as Aadhaar seeding becomes near universal (it had exceeded 99% by May 2018, a year after follow-up 1).

We also examine heterogeneity along several additional pre-specified dimensions, including (i) characteristics likely to matter for understanding the distributional and political consequences of the reform such as caste, education level, income level, and baseline satisfaction with the PDS, and (ii) characteristics of the location likely to predict heterogeneity in the implementation of the reform such as rural status, cellular network signal strength, the device mode (online, partially online, or offline), and beneficiaries’ subjective ratings of their dealers at baseline.<sup>30</sup> In general we find limited evidence of heterogeneity along these dimensions (Tables A.11, A.12, A.13, and A.14.). There is some evidence that wealthier and better-educated households receive differentially more value and that wealthier households incur larger increases in transaction costs. Finally, effects were *not* more negative in areas with relatively weak connectivity or when machines operated in online mode. This is notable as the risk that Aadhaar’s connectivity requirements were ill-suited to remote parts of rural India has been a common concern. In practice, the main source of exclusion from ABBA appears to have been unseeded beneficiaries rather than poor connectivity.

## 4.4 Impacts on dealers

We asked dealers about their profitability and expectations of future business prospects (Table 6). Dealers report a significant 18% fall in the profitability of selling rationed commodities. Since (as we have seen) disbursements had not changed, this most likely reflects increased

---

<sup>29</sup>A potential longer-term consequence of not seeding a ration card is that the government might remove the card from the roster of beneficiaries entirely; 144,161 cards (6% of the total) were deleted between October 2016 to May 2018, three times the proportion removed in the previous 2 year period. Based on non-experimental analysis using data collected after our experiment, we find that unseeded cards were more likely to belong to “ghosts”, and were much more likely to be deleted than seeded ones (36% vs. 2%). Yet, because the overall number of ghosts were small, a large fraction (88%) of deleted cards belonged to genuine non-ghost households. While purely descriptive, the deletions data illustrate another way in which attempts to reduce leakage may have come at the cost of exclusion error of genuine households. See Muralidharan et al. (2020) for further details.

<sup>30</sup>Device mode was not randomly assigned; we identify heterogeneous effects under the assumption that if treated earlier a control FPS would have used the same mode to which it was ultimately assigned. See notes to Table A.13.

awareness of the imminent onset and likely consequences of reconciliation.<sup>31</sup> Roughly the same share of treated dealers expect to continue running their FPS (Columns 1-2), but they predict that the going price to obtain a dealer’s licenses in the first place will drop substantially, by 72% (Columns 3-4). We interpret this result cautiously given that it is a sensitive question and only a minority of dealers provided an answer. That said, it again suggests that dealers in treated blocks anticipated that the government would soon begin using authenticated transaction data to reconcile commodity balances and that this would meaningfully reduce their ability to divert grain onto the open market. Finally, we also asked about expected payments to renew a license, but these turn out to be negligible and unaffected by treatment (Columns 5-6).

## 5 Reconciliation

GoJH’s stated policy was to begin basing all disbursements of rice and wheat to FPSs on the reconciliation of authenticated transaction records starting in July 2017. We examine the implementation of this reform quantitatively in Appendix E using official records on entitlements, disbursements, offtake and stock. We see that reconciliation did have some bite, in the sense that dealers who held larger recorded balances were issued less grain. Yet it was less punitive in practice than on paper, with dealers under-penalized for large recorded stock balances and with these balances themselves falling unexpectedly quickly. Both of these effects grow stronger over time, so that by the end of the reconciliation period implementation was quite weak. This is consistent with anecdotal reports that FPS dealers pressed for and were often granted adjustments or exceptions to offset reconciliation’s effects. The results that follow should thus be interpreted as the effect of the rules as actually implemented, net of these adjustments and exceptions.

### 5.1 Effects on value transfer

The onset of reconciliation coincided with a sharp drop in both disbursements and receipts of reconciled commodities (rice and wheat), but not of unreconciled ones (sugar, salt and kerosene). Figure A.3 illustrates this, plotting the evolution of value disbursed (Panel (a)) and received (Panel (b)) separately for reconciled and unreconciled commodities. It also overlays the raw data with the fit we obtain from estimating Equation 2 and 95% confidence

---

<sup>31</sup>Treated dealers may also have *already* reduced black market sales and increased their stores of grain, anticipating that these might be needed once reconciliation began.

bands around this fit.<sup>32</sup> For both series our pre-specified functional form fits the temporal patterns quite well. For reconciled commodities, both value disbursed and received show little change until the onset of reconciliation, after which both drop sharply. They then rebound gradually until October, before GoJH suspended reconciliation in November (see more below). For unreconciled commodities both value disbursed and received drift slightly downwards over time without any substantial change during the period of reconciliation; if anything they are somewhat higher than trend.

The dynamics of value disbursed are in line with the government’s plans. GoJH’s view was that dealers should have been holding grain stocks equivalent to the opening balances of undistributed grains recorded on the ePOS machines at the start of the reconciliation period and would initially be able to meet obligations to beneficiaries by drawing these down, after which they would require fresh disbursements. As a corollary, disbursements from GoJH to FPSs would fall initially but then gradually rebound, which is what we see in the data. As per the government’s intentions, beneficiaries should not have been affected in this scenario as dealers would be able to fully supply grains in spite of the temporarily reduced flow of new disbursements from GoJH by drawing down their retained stocks.<sup>33</sup>

In other words, GoJH had already started treating undistributed grains (as seen in ABBA records) as savings that were on the books of the FPS dealers. Reconciliation was simply the process by which GoJH aimed to convert the “notional” savings into “real” savings by reducing grain disbursal. Thus, GoJH hoped to squeeze rents out of the system without adversely affecting beneficiaries. In the data, however, we see that a meaningful share of the drop in disbursements was passed through to beneficiaries in the form of lower value received. In Table 7 we quantify these effects by treatment arm. Figure 3 provides the corresponding plots split by treatment arm.

Even when receiving less than their entitlement, beneficiaries potentially had an incentive to “sign” biometrically for more than they received. This is because (as discussed in Appendix C) under reconciliation the amount of grain available to be divided with the FPS dealer next month was increasing in the amount they agreed to acknowledge receiving this month. To examine this we match survey data to administrative data on the transactions

---

<sup>32</sup>We value commodities using market prices obtained from follow-up 1, as follow-ups 2 and 3 did not elicit updated market price data. The evolution of value thus reflects the evolution of quantities.

<sup>33</sup>To illustrate, consider a dealer who distributes 85% of his allocation each month, but continues receiving a 100% grain allocation each month. If ePOS records were available for 8 months before reconciliation, the records would show an opening balance of  $8 \times 15\% = 120\%$  of a month’s supply and the government would not disburse any grains in month 1 of reconciliation, as the dealer’s existing stocks should be sufficient for all registered beneficiaries. If the dealer distributes 85% from those stocks in month 1, his opening balance for month 2 would be  $120\% - 85\% = 35\%$ , and the government would disburse 65% of a month’s stock to bring the stock to 100%. By month 3, a new steady state would be reached in which the government disburses 85% each month as opposed to 100% and the dealer continues to distribute 85% to beneficiaries.

conducted by individual households. As anticipated, we see that households systematically report receiving less grain than their authenticated transaction logs indicate (Figure A.5). This underscores the point that authentication reforms such as ABBA, while they may help address identity fraud, do not necessarily prevent simple embezzlement from transfers intended for legitimate beneficiaries.

## 5.2 Why did value received fall?

The meaning of this drop in value received depends on the mechanism driving it: in particular, whether it reflects the one-time large drop in disbursements that in turn reflected the large opening balances that many dealers had accumulated based on ABBA records, or the deeper issues of corruption displacement and bargaining power described in Section 2.3. To examine this we take advantage of the fact that dealers experimentally assigned to receive ABBA early had ePOS devices for a longer time and were thus held responsible for larger opening balances when reconciliation began. Figure A.4 illustrates this, plotting the distribution of total grain stocks at end of June for the treatment and control group separately. On average, the government held treated shops responsible for 7,715 kg of undistributed grain as opposed to 3,346 kg for control shops ( $p < 0.0001$ ). Thus, disbursements should have fallen more in treated areas, and if treated dealers had already diverted these stocks, beneficiaries would likely get less grain as well.<sup>34</sup>

Consistent with this reasoning, the effects of reconciliation were more pronounced in treated areas (Table 7). Value of reconciled commodities (rice and wheat) disbursed to treated blocks fell by Rs. 182 (or 37% of the pre-reconciliation mean in Table 2), in the first month of reconciliation (Panel A). Of this, value received by legitimate beneficiaries fell by 34% (Rs. 62) (Panel B), while the remaining 66% represents a reduction in leakage (Panel C). Averaging over the full 4-month period of reconciliation, we estimate that disbursements were Rs. 86 (17%) lower per month than they otherwise would have been, and that of this drop 49% was passed on as a reduction in benefits, with the remaining 51% representing a reduction in leakage.

In the control group, on the other hand, value disbursed fell by Rs. 92, or 19%, in the first month of reconciliation (Panel A). Of this, an estimated 22% (Rs. 20) represents a reduction in value received by legitimate beneficiaries (Panel B), while the remaining 78% represents a reduction in leakage (Panel C). While still substantial, these figures are significantly smaller than the corresponding figures for treated areas. Averaging over the full 4-month period of reconciliation, we estimate that disbursements were Rs. 46 (9%) lower per month than they

---

<sup>34</sup>In principle, dealers could have purchased grains to make up for stocks they had diverted. In practice, they would have had to pay out of pocket for this and we did not hear any anecdotes of it happening.

otherwise would have been, and that of this drop 34% was passed on as a reduction in benefits, with the remaining 66% representing a reduction in leakage.

On the extensive margin, the share of beneficiaries receiving no value increased by 13 percentage points and 4.3 percentage points in treated and control blocks, respectively (Table 7). To calculate the implied total increase in exclusion among beneficiaries for whom our data are representative, we assume that non-study districts received ABBA at the same time as our treated blocks, in line with the government’s desire to roll ABBA out quickly. Under this assumption we estimate that 1.7 million additional people did not receive PDS benefits during the first month of reconciliation. Even under the more conservative assumption that non-study districts were held back and did not receive ABBA until our control blocks did, we estimate that 1.2 million additional people were excluded.<sup>35</sup>

Building on this comparison, we can use experimental assignment as an instrument for opening balances in order to predict the impact reconciliation would have had if ration shops had held *no* opening balances (or equivalently, if reconciliation had been introduced on a “clean-slate” basis – whereby dealers were not held responsible for several prior months of undistributed grain stocks). Specifically, we estimate Equation 2 fully interacted with the FPS-level stock balance as of the beginning of July 2017, expressed per ration card (the “opening balance”). The main effect of reconciliation is then the predicted effect on a ration shop with an opening balance of zero. This exercise involves a degree of extrapolation, but not to an implausible degree. Zero is within the support of the actual distribution of opening balances, and near to the rest of its mass: 64% of ration shops had opening balances less than one month’s entitlement and 15% had opening balances less than 10% of one month’s entitlement (Figure A.4).

We instrument for the opening balance (and its interactions) with assignment to treatment (and its interactions). The first stage in this specification is thus a difference-in-differences model where one dimension is time and the other is treatment. This instrument is valid if *past* exposure to ABBA altered the effects of reconciliation only through its effects on opening balances, *conditional* on contemporaneous use of ABBA, which was universal by the time reconciliation began. Minimum *F*-statistics are comfortably above weak instrument thresholds for our primary outcomes (bottom panel of Table 8).

The results suggest that absent any opening balance effects reconciliation by itself would have had no negative effects on beneficiaries. If anything, the point estimates on value received are (insignificantly) positive (by Rs. 9.3, Column 4 in Table 8). However, the inter-

---

<sup>35</sup>If non-study districts were like treated blocks then we estimate that  $13\% \times 12.32$  million = 1,602,000 people in treatment blocks and  $4.3\% \times 2.77$  million = 119,000 people in control blocks were excluded for a total of 1.7 million. If instead they were like control blocks then we estimate that  $13\% \times 6.25$  million = 812,000 and  $4.3\% \times 8.85$  million = 380,000 people were excluded for a total of 1.2 million.

action of reconciliation with opening balance is significantly negative, implying that it was the opening balances for which dealers were held accountable rather than the reconciliation policy per se which led to the drop in benefits received. Turning to value disbursed, the estimates suggest that value disbursed would have declined by Rs. 76 per ration card (Column 1). These results correspond to a 17.3% reduction in leakage relative to the average monthly value disbursed in January 2017, and a 98.9% reduction relative to mean leakage.<sup>36</sup>

Put together, these results suggest that it *may* have been possible for GoJH to squeeze dealer rents and cut leakage substantially without hurting beneficiaries had it conducted a “clean-slate” reconciliation – that is, held dealers accountable for undistributed grain stock going forward but not for past stocks (which may have already been diverted). Interpreted through the lens of our theoretical framework, the results also suggest that requiring that beneficiaries “sign” biometrically for grain for dealers to get credit for distributing it did not harm and may have improved beneficiaries’ negotiating position.

Looking ahead, our results suggest that in the longer-run steady state, ABBA and reconciliation *could* yield positive social returns by squeezing intermediary rents without decreasing beneficiary bargaining power. In particular, Aadhaar-seeding rates had exceeded 99% by May 2018, and reconciliation in steady-state will by construction be a monthly as opposed to cumulative exercise, which is closer to the “clean-slate” calculations we show above. Going further, authentication and real-time transaction data also allow the government to make PDS benefits portable and accessible at *any* FPS and not just the assigned one, which might further enhance beneficiary bargaining power (as for example in (Shleifer and Vishny, 1993) analysis of competitive bribe-setting). Making the PDS nationally portable is a current priority of the Govt. of India. At the same time, our results on exclusion also highlight the need for caution and gradualism in the implementation of such logistically complex reforms.

## 6 Discussion and conclusion

Social programs worldwide must navigate a trade-off between fraud and corruption on one hand, and excluding legitimate beneficiaries on the other. This is especially so in developing countries where programs are implemented by potentially corrupt intermediaries, state capacity is limited, and lives may literally be at stake. Hoping to improve the terms of this tradeoff, policy-makers are increasingly investing in better identification technologies and requiring more stringent identity verification standards for accessing welfare benefits.

---

<sup>36</sup>January 2017 is the first month in the first follow-up survey with matched disbursement-receipts data. As seen in Table 8, the reduction in leakage due to reconciliation is Rs. 85.3 (disbursements fell by Rs. 76 and receipts increased by Rs. 9.3), which is 17.3% of total value disbursed (Rs. 493) and 98.9% of mean leakage ( $493 - 407 = 86$ ).

This paper has examined the consequences of a major effort to reduce leakage in the context of India’s largest welfare program, the PDS. The Government of Jharkhand introduced stricter authentication of transactions using the flagship national ID scheme, Aadhaar, and then used the resulting authenticated transaction data to reconcile shipments of grain to intermediaries (in effect, reducing subsequent shipments to dealers who could not show they had distributed earlier shipments to intended beneficiaries).

The episode illustrates the collateral damage that a crackdown on corruption can cause. Authentication on its own had no measurable benefit: it excluded some beneficiaries, increased transaction costs for others, and did not reduce leakage. Leakage did fall once the government introduced reconciliation, but at the cost of additional exclusion. All told we estimate that 1.5-2 million beneficiaries lost access to benefits at some point during the roll-out of these reforms—contributing to political backlash that ultimately led the government to suspend reconciliation entirely.

Both supporters and critics of these reforms were thus correct to some extent. Leakage fell meaningfully, but at the cost of a meaningful increase in exclusion. But the results should not be read as a verdict on Aadhaar per se, since we study a transition period when the reform was being introduced. We emphasize instead the broader lesson that the effects of a technology such as biometric authentication depend heavily on how it is used.

We see this to some extent within our own data. Exclusion due to reconciliation could arguably have been less severe, for example, had the government conducted reconciliation on a “clean-slate” basis instead of holding dealers accountable for their historical (mis)behavior. And we see it when comparing the results to those from our own earlier work in Andhra Pradesh (AP), where we studied the application of biometric authentication to its employment and pension schemes (Muralidharan et al., 2016). Leakage fell there also, but the money saved was passed on to legitimate beneficiaries who did *better* as a result.

These contrasting distributional consequences reflected differences in design, which in turn reflected political priorities. The emphasis in AP was on improving the beneficiary experience; this was manifest in relatively generous provisions for manual overrides, for example. The emphasis in Jharkhand was on reducing fraud and generating fiscal savings; it provided less generous override provisions. Indeed, the Jharkhand reforms took place within a broader political climate in which the central government was pushing to deliver on its promises to crack down on fraud, even if this came at the cost of some painful exclusion.<sup>37</sup> More generally, the contrasting results highlight the need to caution against simplistic characterization

---

<sup>37</sup>For instance, the demonetisation that the central government introduced at around the same time, which created significant economic disruption in an effort to curtail the shadow economy (Chodorow-Reich et al., 2020), illustrates the same governing philosophy.

of the impacts of new technologies on governance outcomes without paying close attention to the details of program and intervention design.<sup>38</sup>

The contrasting consequences also echo old debates about gradualism versus “shock therapy” in introducing major reforms. AP took a more gradual approach: even two years after the roll-out of the reform began, for instance, fewer than 50% of payments were biometrically authenticated (the rest being manual). In contrast, Jharkhand drove rapid adoption by making biometric authentication mandatory. Just six months after rollout began, over 90% of households reporting that transactions were being authenticated. This push for speed may have contributed to a relatively disruptive and unpopular rollout. An overwhelming 93% of survey respondents had a favorable opinion of the AP Smartcards program, compared to only 44% in Jharkhand (Table A.16).

Practically speaking, our results highlight the need to guard against exclusion when designing anti-corruption reforms. With respect to identification, for example, the right design in some cases may be to periodically authenticate beneficiary lists rather than individual transactions.<sup>39</sup> Where transactions must be authenticated (to enable benefit portability, for example), effective fallback methods of authentication or override mechanisms become important.<sup>40</sup> And real-time monitoring of reforms as they roll out can help to detect and quickly address harms to beneficiaries. One promising approach is simply to call them: Muralidharan et al. (2021) provide evidence that this may be a scalable way to measure and improve last-mile service delivery. We discuss these issues further in Muralidharan et al. (Forthcoming), which reviews Aadhaar deployments in social programming in India specifically and interprets these through the lens of a more general framework for weighing the costs and benefits of biometric authentication in transfer programs.

---

<sup>38</sup>There are close parallels with the literature on education technology, where impacts on learning outcomes have been found to vary widely as a function of design details (Muralidharan et al., 2019).

<sup>39</sup>This would be akin to the one-time authentication the Government of India required for direct transfer of the LPG subsidies studied by Barnwal (2019), for example. Authenticating every interaction may also be appropriate in cases where physical attendance is an important margin; for example, Bossuroy et al. (2019) find that requiring (non-Aadhaar) biometric authentication in health clinics increased adherence, and reduced over-reporting of adherence, to a tuberculosis treatment regimen.

<sup>40</sup>Aadil et al. (2019) find few reports of exclusion from PDS benefits due to Aadhaar authentication in Krishna district in Andhra Pradesh, which they attribute to the availability of several override mechanisms.

Value received (kerosene)	73.73	68.99	-.85	.72
Beneficiary transaction costs	58.69	3.57	-24.61	.58
Dealer transaction costs	5.08	3.69	.53	.36
<i>Panel C: Program implementation (n = 3578 ration cards)</i>				
Dealer had ePOS machine at EL	.96	.05	.92***	0
Dealer used ePOS in January 2017	.91	.06	.86***	0
Dealer used ePOS in February 2017	.91	.06	.87***	0
Dealer used ePOS in March 2017	.91	.05	.87***	0

This table compares treatment to control blocks within study districts on baseline characteristics (Panel A), survey outcomes (Panel B), and measures of program implementation (Panel C). Column 3 reports the regression-adjusted difference in means, and column 4 reports the *p*-value. “Priority HH” is the number of ration cards assigned to households eligible for PDS; “AAY HH” is the number of ration cards assigned to extremely poor households. “Aadhaar numbers seeded per RC” is the average number of verified Aadhaar numbers seeded per ration card. “Rice disbursed per X HH” is kilograms of rice disbursed per priority and “antyodaya” HH. “Number of FPS” is the total number of FPS. “Median HH size” is the block median number of household members listed on ration cards. “% of HH with least one Aadhaar seeded” is an indicator equal to one if the household had at least one Aadhaar number seeded to its ration card. “% of HH missing any Aadhaar seeded” is an indicator equal to one if we do not observe the count of Aadhaar numbers seeded to the ration card. “Value received” is the ration card-month rupee value received for each commodity. “Transaction costs” are the time and money costs incurred by attempting to purchase (transport) PDS commodities for the beneficiary (dealer). “Dealer has an ePOS machine at endline” is an indicator equal to one for endline survey respondents who reported that their FPS dealer had an ePOS machine. “Dealer used an ePOS machine in Month X 2017” is an indicator equal to one for endline survey respondents who reported that their FPS dealer used or attempted to use an ePOS machine in the corresponding month. Regressions include strata FEs, and are weighted by inverse sampling probabilities where appropriate. Statistical significance is denoted as: \**p* < .10, \*\**p* < .05, \*\*\**p* < .01.

% of sample	88	89	90	90	90	89

This table reports estimated treatment effects on the value of commodities disbursed by the government (Panel A), received by recipients (Panel B), and the difference (Panel C) in endline one (January–March). The unit of measurement is rupees per ration card-month throughout. In Panel A the unit of observation is FPS  $\times$  month and we use the universe of FPSs; in Panels B and C the observation is the ration card  $\times$  month and a representative sample of ration card holders in Panels B and C. The dependent variable in columns 2-6 is the relevant quantity of the commodity multiplied by the difference between the median market price of that commodity in control blocks in the same district, and the statutory PDS price for that commodity. The dependent variable in column 1 is the sum of the values in columns 2-6. In Panel C, estimated effects are the difference between estimated effects on block-level mean value disbursed per ration card and value received per ration card, estimated within a Seemingly Unrelated Regression framework. All specifications include strata fixed effects and the baseline value of the dependent variable. Standard errors clustered at the block level are reported in parentheses, with statistical significance denoted as: \* $p < .10$ , \*\* $p < .05$ , \*\*\* $p < .01$ .  $q$  values adjusted to control the false discovery rate across the five commodities are reported in brackets.

Table 3: Effects on transaction costs

	Beneficiary costs	(2)	Dealer costs	(3)	Government costs	(4)
	(1)					
Treatment	6.9* (3.8)	.51 (.95)	.65 (.63)		6.2 –	
Adjusted R <sup>2</sup>	.09	.10	.28		–	
Reference group mean	41	6.8	5.9		144	
Observations	3,538	441	367		–	
% of sample	89	–	93		–	
Sample	–	Full	Restricted		–	

This table reports estimated treatment effects on measures of transaction costs incurred in transferring PDS commodities. In column 1 the unit of analysis is the ration card and the dependent variable is the total cost incurred in March by the household holding that ration card in purchasing or attempting to purchase PDS commodities, including time and money costs (see text for details). In columns 2 and 3 the unit of analysis is the FPS and the dependent variable is the total cost incurred by the dealer to transport and store PDS commodities in an average month in January–March divided by the number of ration cards assigned to that dealer. In column 2 the sample includes all dealers surveyed, including those to whom sampled households switched between baseline and endline; in column 3 it includes only dealers drawn in the original sample. Column 4 reports the mean administrative cost per ration card  $\times$  month incurred by the state government to administer ABBA based on vendor costs in treatment areas only (not a treatment effect). All specifications include strata fixed effects, and regressions in columns 1-3 include the baseline value of the outcome variable. Standard errors clustered at the block level are reported in parentheses with statistical significance denoted as: \* $p < .10$ , \*\* $p < .05$ , \*\*\* $p < .01$ .

Table 4: Effects on the extensive margin of value received

	<u>Any Commodity</u>	<u>Rice</u>	<u>Wheat</u>	<u>Sugar</u>	<u>Salt</u>	<u>Kerosene</u>
	(1)	(2)	(3)	(4)	(5)	(6)
Treatment	-.024* (.014)	-.025 (.016) [1.00]	-.064 (.047) [1.00]	-.011 (.019) [1.00]	.0049 (.018) [1.00]	-.013 (.018) [1.00]
Adjusted R <sup>2</sup>	0.10	0.10	0.32	0.05	0.04	0.10
Control mean	.85	.83	.28	.28	.29	.75
Observations	10,396	10,557	10,654	10,670	10,726	10,618
% of sample	88	89	90	90	90	89

This table reports the estimated treatment effect on the extensive margin of the values received by beneficiaries per month in endline one (January–March). The unit of analysis is the ration card-month. The dependent variable in columns 2-6 is an indicator equal to one if the ration card holder received a positive quantity of the commodity in a given month. The dependent variable in column 1 is an indicator of whether the household received a positive quantity of any commodity in a given month. All regressions include strata fixed effects and the baseline value of the dependent variable. Standard errors clustered at the block level are reported in parentheses, with statistical significance denoted as: \* $p < .10$ , \*\* $p < .05$ , \*\*\* $p < .01$ .  $q$  values adjusted to control the false discovery rate across the five commodities are reported in brackets.

Table 5: Heterogeneous effects by Aadhaar seeding

	At least one Aadhaar seeded? (BL)		At least one Aadhaar seeded? (Oct 2016)		
	No ( <i>N</i> =797) (1)	Yes ( <i>N</i> =2645) (2)	No ( <i>N</i> =208) (4)	Yes ( <i>N</i> =3607) (5)	
		$\Delta$ (3)		$\Delta$ (6)	
Value received (market prices)	-49*** (18) {390}	.054 (14) {509}	49*** (15)	2.1 (12) {478}	225*** (26)
Value received > 0	-.1*** (.024) {.85}	-.023 (.015) {.91}	.079*** (.022)	-.017 (.013) {.9}	.39*** (.051)
Value received (WTA)	-31 (36) {991}	37* (22) {1159}	68* (35)	19 (22) {1134}	16 (74)
Transaction costs	6.8 (6.6) {54}	8.9** (4.3) {41}	2.1 (6.9)	6.2 (3.9) {41}	-.12 (13)
Observations	3096	3096	3434	3434	3434

This table reports estimated differential treatment effects by Aadhaar seeding status in endline one (January–March). Column 1 (2) reports estimated treatment effects for households that did not (did) have at least one member with an Aadhaar number seeded to their ration cards at baseline. Column 3 reports the difference between these effects. In columns 4-6, we compute the same treatment effects and differences, but focus instead on households with at least one seeded Aadhaar number in October 2016, our closest estimate to endline 1 (January - March 2017). Each row represents a different primary outcome; all estimates are derived from a single underlying regression that interacts treatment with an indicator equal to one for households with one or more Aadhaar numbers seeded. All specifications include strata fixed effects and the baseline value of the dependent variable when available. Standard errors clustered at the block level are reported in parentheses with statistical significance denoted as: \* $p < .10$ , \*\* $p < .05$ , \*\*\* $p < .01$ . Control means are reported in curly brackets.

Table 6: Effects on dealer expectations

	Intends to continue running FPS?		Expected bribes to obtain license?		Expected bribes to renew license?		Profit (self-reported)	
	(1)	(2)	(3)	(4)	(5)	(6)	(7)	(8)
Treatment	.054 (.055)	.033 (.059)	-56,816** (28,561)	-58,393* (33,370)	-111 (123)	-83 (147)	-1,244** (531)	-1,121* (583)
Adjusted R <sup>2</sup>	.093	.13	.31	.27	.053	.035	.07	.051
Control mean	.73	.71	76,590	81,188	565	555	5,891	6,113
Observations	437	366	150	127	370	307	445	370
% of sample		92		32		78		93
Sample	Full	Restricted	Full	Restricted	Full	Restricted	Full	Restricted

This table reports estimated treatment effects on measures of FPS dealers' expectations in March about the future. The unit of analysis is the FPS. The dependent variable in columns 1-2 is an indicator equal to 1 if the dealer responded "yes" when asked whether they intended to continue running an FPS for the next two years and to 0 if they responded "maybe" or "no." The dependent variable in columns 3-4 is the dealer's estimate of the additional money (excluding official fees) someone would have to pay to obtain a new license to operate a FPS. The dependent variable in columns 5-6 is the dealer's estimate of the additional money (excluding official fees) an existing FPS dealer would have to pay to renew his or her license. The dependent variable in columns 7-8 is the dealer's self reported estimated profit. In columns 1, 3, 5 and 7 the sample includes all dealers surveyed, including those to whom sampled households switched between baseline and endline; in columns 2, 4, 6 and 8 it includes only dealers drawn in the original sample. All specifications include strata fixed effects. Standard errors clustered at the block level are reported in parentheses with statistical significance denoted as: \* $p < .10$ , \*\* $p < .05$ , \*\*\* $p < .01$ .

Table 7: Effects of reconciliation

	Reconciled			Unreconciled		
	Treatment	Control	Difference	Treatment	Control	Difference

January 2017 mean	.84	.85		.82	.81	
Observations	25,469	13,447		25,349	13,334	
% of sample	89	91		88	90	

This table reports estimates of the effect of reconciliation on measures of the value disbursed by the government (Panel A), received by recipients (Panel B), the difference (Panel C) separately for treatment and control areas, and the effect of reconciliation on the extensive margin (Panel D) using data from all three endlines. The unit of analysis is the FPS-month in Panel A and the ration card-month in Panels B, C, and D but all figures are per ration card-month. Observation counts vary by panel because we use the universe of FPSs to estimate effects on disbursements in Panel A, and a representative sample of ration card holders in Panels B, C, and D, but all samples are representative. The dependent variable in columns 1 and 2 is the sum of values for rice and wheat, and the dependent variable in columns 4 and 5 is the sum of values for sugar, salt, and kerosene. Per-commodity values are defined in the notes to Table 2 above. Columns 3 and 6 test the difference between columns 1, 2 and 4, 5, respectively. Standard errors clustered at the FPS level are reported in parentheses, with statistical significance denoted as: \* $p < .10$ , \*\* $p < .05$ , \*\*\* $p < .01$ .

Table 8: Heterogeneous effects of reconciliation on value disbursed and received by FPS balance

	Value disbursed			Value received		
	(1) Total	(2) Rice	(3) Wheat	(4) Total	(5) Rice	(6) Wheat
Reconciliation	-76*** (6)	-47*** (5.1)	-24*** (3)	9.3 (17)	5.1 (14)	-3.4 (4.8)
Reconciliation*Balance	-.29*** (.013)	-.33*** (.013)	.034 (.064)	-.13*** (.034)	-.12*** (.031)	.0027 (.1)

Observations	92489	95581	93258	35518	36269	36046
% of frame/sample	91	94	92	82	83	83
Min. F-stat	283	290	24	14	14	3
Min. S-W F-stat	628	636	92	53	54	6

This table reports differential effects of accumulated stock balance at the time of reconciliation onset (July 2017) on value disbursed by dealers (columns 1–3) and received by beneficiaries (columns 4–6). The unit of analysis is the FPS-month for columns 1–3 and ration card  $\times$  month for columns 4–6. Observation counts vary because we use the universe of FPSs to estimate effects on disbursements in columns 1–3, and a representative sample of ration card holders in columns 4–6, but both samples are representative. The dependent variable in columns 2, 3, 5, and 6 is the per-commodity value disbursed and received as defined in the notes to Table 2 above. The dependent variable in column 1 is the sum of the values from columns 2 and 3, and the dependent variable in column 4 is the sum of values in columns 5 and 6. We calculate average balance per ration card as the balance per FPS at the beginning of July 2017, provided by NIC, divided by ration card counts per FPS, and we instrument for this FPS-level average balance per ration card using the block’s initial ePOS treatment assignment. Standard errors clustered by the FPS level (as pre-specified in our PAP) are reported in parentheses; clustering at the block level only affects significance levels for some coefficients in column 3, with statistical significance denoted as: \* $p < .10$ , \*\* $p < .05$ , \*\*\* $p < .01$ . All regressions include the same set of exogenous covariates: a monthly time trend and its interaction with opening balance, an indicator of the post-reconciliation period and its interaction with opening balance, and strata fixed effects and their interactions with treatment. For each outcome we include the smallest F-statistic and smallest Sanderson-Windmeijer F-statistic over all the instruments in the first stage regression (Sanderson and Windmeijer, 2016).

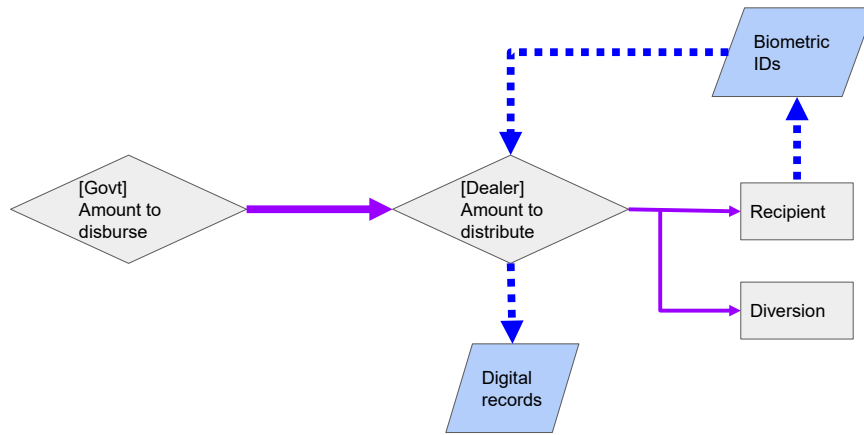

Figure 1: Intervention representation

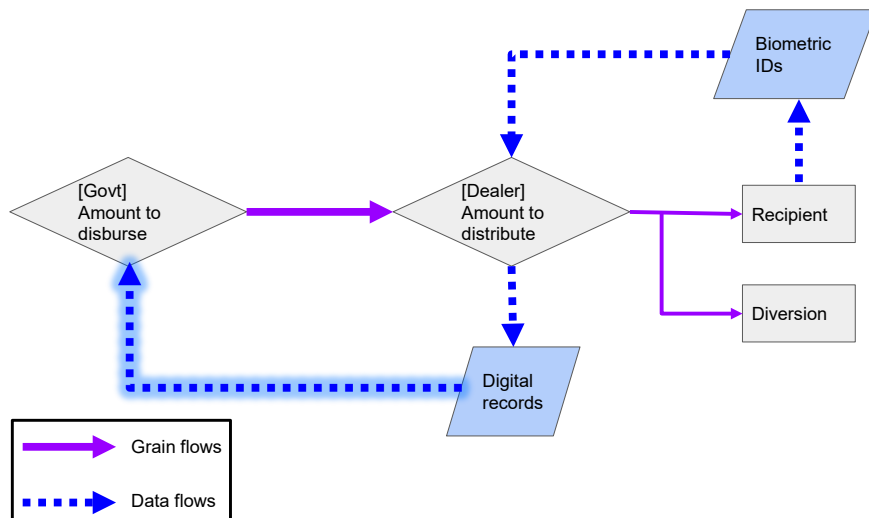

(a) Status quo

(b) ABBA

(c) ABBA + Reconciliation

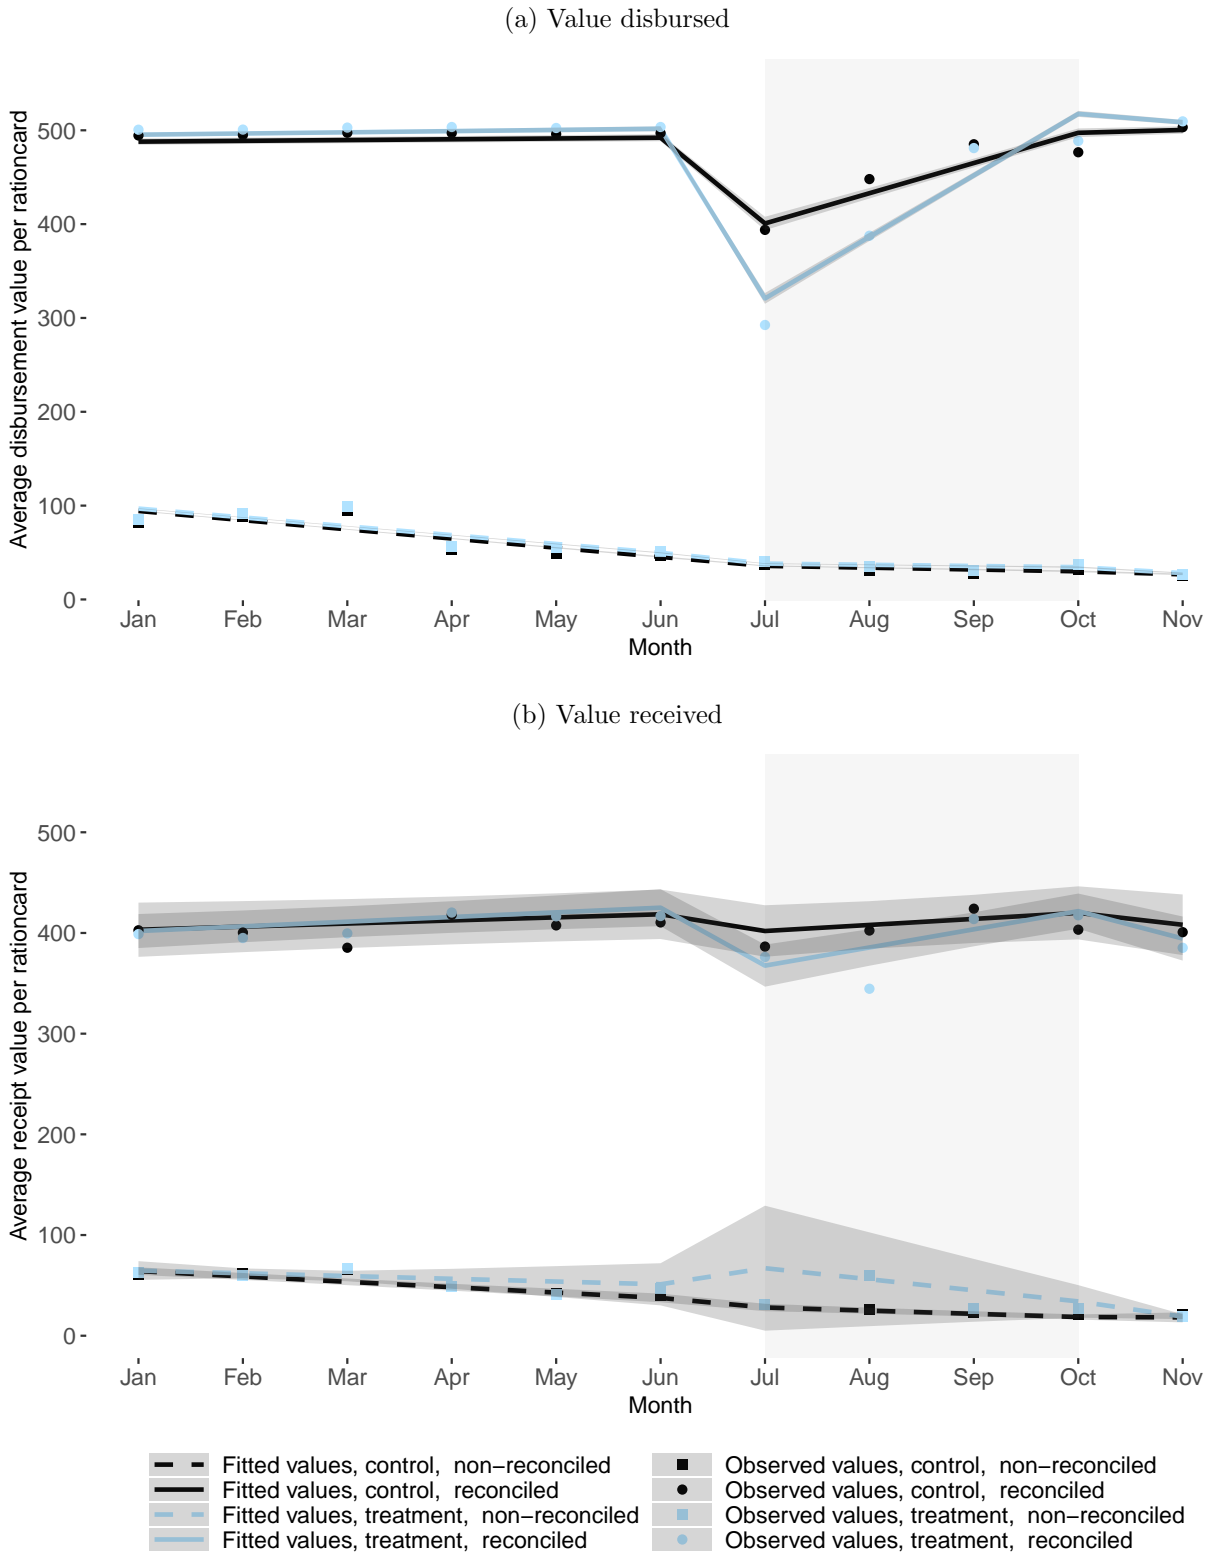

Panel A: In the status quo, the government sends grain each month to the Fair Price Shop (FPS) based on the official entitlement of the number of beneficiaries attached to that particular FPS. Authentication of beneficiaries – if any – is based on paper ration cards, and the previous month’s distribution has no effect on the amount of grain disbursed this month. Panel B: With Aadhaar-Based Biometric Authentication (ABBA), FPS owners authenticate beneficiaries using portable Electronic Point of Sale (ePoS) machines; again, previous distribution has no impact on grains sent. Panel C: With reconciliation added to ABBA, digital records of distribution are sent to the government. Now, if the FPS distributed only 1 sack of grain out of 2 it received in Month 1, in Month 2 the government will only disburse 1 sack of grain to replenish distributed stock.

Figure 2: Value received as a proportion of entitlement

This figure plots the empirical cumulative distribution, separately for households in treatment and control blocks, of value received divided by value entitled per month, pooling the months of January, February, and March 2017. To improve legibility we right-censor the distributions at the 90th percentile.

Figure 3: Effects of reconciliation on value disbursed and received, by treatment

This figure plots the evolution of the average value of commodities disbursed (Panel A) and received (Panel B) by treatment status from January to November of 2017. The unit is the ration card-month. Value disbursed and value received are as described in Figure A.3. Points represent the raw data, while solid lines and dashed lines represent fitted values obtained by estimating Equation 2 for commodities that were and were not subject to reconciliation, respectively. The shaded bands represent 95% confidence intervals for the fitted values. Values are shown separately for the treatment group (blue) and control group (black). The shaded region from July to November indicates the period of reconciliation.

## A Supplemental exhibits

FOR ONLINE PUBLICATION ONLY

Table A.1: Representativeness within Jharkhand

	Study district	Non-study district	Difference	<i>p</i> -value
	(1)	(2)	(3)	(4)
<i>Panel A: 2011 Census</i>				
Population in 2011	1, 267, 604	1, 450, 864	-183, 260	0.50
Population growth, 2001-2011	0.23	0.24	-0.02	0.56
Population density	451	459	-8	0.94
% Literate	0.62	0.66	-0.04	0.22
<i>Panel B: Beneficiary List</i>				
Ration cards per FPS	308	293	15	0.45
Beneficiaries per FPS	981	1, 041	-60	0.33
% FPS rural	0.92	0.89	0.03	0.39
% AAY beneficiares	0.18	0.18	0	0.92
Number of blocks	13.20	12	1.20	0.58
<i>Panel C: NSS 68</i>				
% With salary income	0.11	0.16	-0.04	0.25
Monthly per capita consumption	1, 097	1, 298	-201	0.10
Consumption value food	4, 050	3, 518	532	0.34
Consumption value fuel/light	506	462	44	0.16
N	10	14		

This table compares the 10 districts studied with the remaining 14 districts in Jharkhand using data from the 2011 and 2001 Censuses (Panel A), the PDS beneficiary list prior to baseline (Panel B), and the 68th Round of the National Sample Survey (NSS 68) (Panel C). Column 3 reports the raw difference in means between columns 1 and 2. Column 4 reports the *p*-value from a test of equality of means. “Population density” is in population per square mile. “Ration cards per FPS” is the ratio of PDS ration cards to the number of FPSs. “Beneficiaries per FPS” is the ratio of PDS ration cards to the number of FPSs. “% FPS rural” is the share of FPSs located in areas classified as rural. “% AAY beneficiaries” is the percentage of PDS beneficiaries covered by the more generous Antyodaya Anna Yojana (AAY) scheme. “% With salary income” is the share of the population that reports earning a salaried income. “Monthly per capita consumption” is household monthly per capita consumption in Rs. “Consumption value food” is household monthly expenditure on food in Rs. “Consumption value fuel/light” is the household monthly expenditure on fuel and lighting in Rs. Statistical significance is denoted as: \**p* < .10, \*\**p* < .05, \*\*\**p* < .01.

Table A.2: Comparison of dealer samples

	Original sample	Additional sample	Regression- adjusted difference	<i>p</i> -value
	(1)	(2)	(3)	(4)
Treatment	.67	.77	−.08*	.07
Age	44.01	43.30	1.51	.33
Years of education	9.81	9.97	−.22	.74
Has an FPS dealer in family	.13	.27	−.12	.18
Years as FPS dealer	14.26	14.07	−.09	.95
Has other income sources	.79	.73	.07	.32
Runs FPS out of own home	.61	.73	−.16*	.06
Days open per month	18.73	19.80	−1.37*	.10
Hours open per day	6.75	6.74	−.07	.80
Days mandated to be open per month	23.46	24.05	−.58	.56
Hours selling PDS commodities per day	6.51	7.27	−.78	.50
Hours mandated to be open per day	6.93	7.01	.01	.97
Number of total ration cards	268.75	291.34	−20.02	.51
Number of PH ration cards	225.10	249.39	−20.72	.46
Number of AAY ration cards	43.65	41.96	.70	.89
Number of villages	2.05	2.45	−.38	.12

This table compares the PDS dealers originally sampled at baseline (“original sample”) with those added at the first endline as a result of ration card re-assignment across ration shops (“additional sample”). Columns 1 and 2 report the means of each variable for the respective groups. Column 3 reports the coefficient from a regression of the given variable on an indicator for being in the original sample, controlling for strata fixed effects, and column 4 reports the *p*-value for a test that this coefficient is zero. Estimates are weighted by inverse sampling probabilities. Statistical significance is denoted as: \**p* < .10, \*\**p* < .05, \*\*\**p* < .01

Table A.3: Response rates

	Treatment (1)	Control (2)	Difference (3)	<i>p</i> -value (4)
Ever Surveyed	0.97	0.97	-0.00	0.67
Surveyed at:				
Baseline	0.87	0.84	0.01	0.30
Endline 1	0.90	0.90	-0.02*	0.09
Endline 2	0.91	0.91	-0.01	0.22
Endline 3	0.91	0.90	-0.00	0.81
Confirmed Ghost	0.01	0.02	-0.01	0.14
Unknown	0.01	0.01	0.01**	0.04

This table reports survey response rates for all households by arm. Columns 1 and 2 report treatment and control group means, respectively. Column 3 reports the regression-adjusted difference between these, and Column 4 reports the *p*-value on a test of the null that this difference is equal to zero. Estimates are weighted by inverse sampling probabilities. Statistical significance is denoted as: \**p* < .10, \*\**p* < .05, \*\*\**p* < .01

Table A.4: Composition of attrition from Endline 1

	Difference (1)	<i>p</i> -value (2)
Total access cost in March	0.012	0.55
Average access cost in January - March	0.012	0.55
Average total value received in January - March	0.0061	0.62
Average value received of rice in January - March	0.0058	0.64
Average value received of wheat in January - March	-0.013	0.18
Average value received of sugar in January - March	0.017*	0.05
Average value received of salt in January - March	0.015	0.13
Average value received of kerosene in January - March	0.0022	0.86

This table reports measures of the difference in the composition of attriters from the treatment and control groups between baseline and Endline 1. Specifically, Column 1 reports the coefficient on the interaction between a treatment indicator and the indicated baseline variable in a regression predicting an indicator for response at Endline 1. Coefficients are rescaled by the standard deviation of the baseline variable, so that a coefficient of 0.01 indicates 1% difference in response rates between treatment and control for households with a baseline value of +1 s.d. Each regression also includes the main effects of treatment and the baseline variable. Column 2 reports the *p*-value on a test of the null that the coefficient on this interaction term is equal to zero. Estimates are weighted by inverse sampling probabilities. Statistical significance is denoted as: \**p* < .10, \*\**p* < .05, \*\*\**p* < .01

Table A.5: Missingness: surveyed households

	Treatment (1)	Control (2)	Difference (3)	<i>p</i> -value (4)
Total access cost in March	0.01	0.02	-0.01	0.13
Average access cost in January - March	0.01	0.02	-0.01	0.13
Average willingness to accept in January - March	0.07	0.08	0.00	0.73
Total value received in January - March	0.04	0.04	-0.01	0.49
Average value received of rice in January - March	0.03	0.04	-0.01	0.41
Average value received of wheat in January - March	0.02	0.02	0.00	0.66
Average value received of sugar in January - March	0.01	0.02	-0.01	0.28
Average value received of salt in January - March	0.01	0.02	-0.01	0.28
Average value received of kerosene in January - March	0.02	0.03	-0.01	0.20

This table reports the rate at which primary household outcomes measured in endline one (covering January – March) are not observed, by treatment status. We include only surveyed households. Columns 1 and 2 report the mean of each outcome among treatment and control households, respectively. Column 3 reports the regression-adjusted difference between these, and Column 4 reports the *p*-value on a test of the null that this difference is equal to zero. Estimates are weighted by inverse sampling probabilities. Statistical significance is denoted as: \**p* < .10, \*\**p* < .05, \*\*\**p* < .01

Table A.6: Effects on quantity disbursed, quantity received, and leakage

	Rice	Wheat	Sugar	Salt	Kerosene

Control mean	3.4	.86	.61	.23	.68
Observations	10,557	10,654	10,670	10,726	10,618

This table reports estimated treatment effects on the quantity of commodities disbursed by the government (Panel A), received by recipients (Panel B), and the difference (Panel C) in endline one (January–March). The unit of analysis is the FPS-month in Panel A and the ration card-month in Panels B and C. Observation counts vary by panel because we use the universe of FPSs to estimate effects on disbursements in Panel A, and a representative sample of ration card holders in Panels B and C, but all samples are representative. In Panel C, estimated effects are the difference between estimated effects on quantity disbursed per ration card and quantity received per ration card with block-level mean imputation in a Seemingly Unrelated Regression framework. All specifications include strata fixed effects and the baseline value of the dependent variable. Standard errors clustered at the block level are reported in parentheses with statistical significance denoted as: \* $p < .10$ , \*\* $p < .05$ , \*\*\* $p < .01$ .  $q$  values adjusted to control the false discovery rate across the five commodities are reported in brackets.

Table A.7: Effects on market prices and overcharges

	Total	Rice	Wheat	Sugar	Salt	Kerosene

Treatment		–	–	–	–	.027 (.03)
Control mean		–	–	–	–	18
Observations	.	.	.	.	.	396
<i>Panel D: Overcharges</i>						
Treatment	-2.6 (1.9)	.069 (.24) [1.00]	-.13** (.056) [0.21]	-2.1 (1.7) [0.84]	.016 (.035) [1.00]	-.66 (.51) [0.84]
Control mean	8.2	1.1	.22	.91	.17	6
Observations	9,623	10,183	10,317	10,260	10,375	10,185

This table reports estimated treatment effects on the market prices reported by beneficiaries (Panel A), market prices reported by FPS dealers (Panel B), statutory prices (Panel C), and total overcharges (Panel D) in endline one (January–March). The unit of analysis is the FPS for Panels A and B, the block-month for Panel C, and the ration card-month for Panel D. Prices are in rupees per kilogram except for kerosene, which is priced in rupees per liter. Observation counts vary in panels A and B as we observe outcomes only when at least one household purchased the commodity and when the dealer reported the commodity is sold in the private market, respectively. In Panels A-C the dependent variables are the median market price reported by beneficiaries assigned at baseline to the given FPS, the local market price reported by FPS dealers (Panel B), and the statutory PDS price, respectively. We do not report effects on statutory prices for goods other than kerosene as these did not vary. In Panel D the dependent variable is the amount beneficiaries report paying above what they should have paid for the quantity they received, by commodity in columns 2-6 and in total in column 1. All regressions include strata fixed effects; those in Panels C and D also include the baseline value of the dependent variable. Standard errors clustered at the block level are reported in parentheses with statistical significance denoted as: \* $p < .10$ , \*\* $p < .05$ , \*\*\* $p < .01$ .  $q$  values adjusted to control the false discovery rate across the five commodities are reported in brackets.

Table A.8: Effects on quality of ration received

	Rice	Wheat	Sugar	Salt	Kerosene
	(1)	(2)	(3)	(4)	(5)
<i>Panel A: Adulteration</i>					
Treatment	.0097 (.012) [0.88]	.0074 (.027) [1.00]	.01 (.0079) [0.88]	-.0036 (.0076) [1.00]	-.0019 (.003) [1.00]
Control mean	.087	.068	.028	.033	.0095
Observations	3,308	971	2,305	2,381	3,205
% of sample	84	25	58	60	81
<i>Panel B: Low quality</i>					
Treatment	-.0014 (.0068) [1.00]	.045 (.031) [0.58]	.014 (.0088) [0.58]	-.058** (.029) [0.52]	-.0008 (.0026) [1.00]
Control mean	.036	.069	.056	.38	.0076
Observations	3,329	975	2,319	2,402	3,228
% of sample	84	25	59	61	82

This table reports estimated treatment effects on the quality of commodities received by beneficiaries in endline one (January–March). The unit of analysis is the ration card in both panels. The dependent variable in Panel A is an indicator equal to one if the respondent reported receiving adulterated commodities at least once in the past three months for each of the five commodities. The dependent variable in Panel B is an indicator equal to one if the respondent reported that the overall quality of commodities received over the past three months was “very bad” or “bad” (as opposed to “OK” or “good”) for each of the five commodities. In both panels, observation of the outcome is conditional on the ration card holder purchasing a positive quantity of the commodity during January–March 2017. All regressions include strata fixed effects and the baseline value of the dependent variable. Standard errors clustered at the block level are reported in parentheses, with statistical significance denoted as: \* $p < .10$ , \*\* $p < .05$ , \*\*\* $p < .01$ .  $q$  values adjusted to control the false discovery rate across the five commodities are reported in brackets.

Table A.9: Effects on food security

	Dietary diversity score	Food consumption score
	(1)	(2)
Treatment	-.011 (.061)	.08 (1)
Adjusted R <sup>2</sup>	.05	.10
Control mean	5.7	43
Observations	3,578	3,578
% of sample	90	90

This table reports estimated treatment effects on measures of food security in March. The unit of observation is the ration card. The dependent variable in column 1 is a simple food diversity score defined as the number of groups from which the household consumed any items in the past week. It equals the sum of a series of indicators each equal to one if the household has consumed any items from within a major food group during the previous week. The dependent variable in column 2 is a food consumption score that follows standard World Food Program methodology to calculate a nutrient-weighted sum of the number of times a household consumed items from each of a set of food groups in the last week. Specifically, it is a weighted sum of the number of times the household consumed items from each major food group in the past week, with weights based on the group's nutrient density. The major food groups are: main staples, pulses, vegetables, fruit, meat and fish, milk, sugar, oil, and condiments. The definition of food groups and their weights can be found from the World Food Programme. All regressions include strata fixed effects. Standard errors clustered at the block level are reported in parentheses. Statistical significance is denoted as: \* $p < .10$ , \*\* $p < .05$ , \*\*\* $p < .01$ .

Table A.10: Effects on determinants of beneficiary transaction costs

	Total Cost	Opportunity cost	Unsuccessful trip count	Unsuccessful trip length	Successful trip count	Successful trip length	Transport cost	
	(1)	(2)	(3)	(4)	(5)	(6)	(7)	(8)
Treatment	7.2* (3.8)	6.9* (3.8)	.87* (.5)	.13*** (.024)	.14 (.32)	.016 (.054)	.15 (.092)	-.81 (.52)
Baseline lag		1.6** (.79)						
Adjusted R <sup>2</sup>	.06	.09	.08	.10	.01	.06	.06	.00
Control mean	41	41	11	.13	1.2	1.5	2.3	1.6
Observations	3,538	3,538	3,066	3,565	449	3,565	3,062	3,538
% of sample	90	90	78	91	11	91	77	90

This table reports estimated treatment effects on the costs incurred by beneficiaries to access PDS rations in March 2017. The unit of analysis is the ration card. The dependent variable in columns 1-2 is the total estimated cost as reported in Table 3, and the remaining columns show impacts on its components. The dependent variable in column 3 is the weighted mean opportunity cost in rupees per hour of household members, weighted by the number of trips each household member made to their FPS in March. The dependent variables in columns 4 and 5 are the number of unsuccessful trips made to the ration shop (defined as trips that did not result in the purchase of positive quantities of any rationed commodity) and the average time in hours spent on these trips. Note that our survey asked about both the number of unsuccessful trips made by each individual on the household roster and for the total number of unsuccessful trips taken. When the latter exceeds the sum of the former we attribute the stated total number of trips to household members in proportion to their stated individual number of trips; the results are not sensitive to alternatives. The dependent variables in columns 6 and 7 are the analogous quantities for successful trips. Finally, the dependent variable in column 8 is the average monetary cost in rupees of any transport fees paid to make these trips (e.g. bus fare). Thus, the total cost in column 1 equals to unit opportunity cost \* (total time spent on unsuccessful trips + total time spent on successful trips) + transportation cost \* (number of unsuccessful trips + number of successful trips) = column 3 \* (column 4 + column 5 + column 6 + column 7) + column 8 \* (column 4 + column 6). All regressions include strata fixed effects. Standard errors clustered at the block level are reported in parentheses, with statistical significance denoted as: \*  $p < .10$ , \*\*  $p < .05$ , \*\*\*  $p < .01$ .

Table A.11: Heterogeneous effects by household characteristics

	HH is upper caste?			HH above median education level?			HH above median annual income?		
	(1) No (N=1875)	(2) Yes (N=1705)	(3) $\Delta$	(4) No (N=2083)	(5) Yes (N=1500)	(6) $\Delta$	(7) No (N=1634)	(8) Yes (N=1608)	(9) $\Delta$
Value received (market prices)	-1.4 (15)	-5 (12)	-3.6 (13)	-21 (13)	23* (14)	44*** (13)	-15 (14)	11 (15)	26* (14)
Value received (WTA)	55** (26)	-14 (24)	-69*** (25)	38 (25)	-0.27 (27)	-38 (29)	26 (26)	30 (27)	4.1 (27)
Transaction costs	4.5 (4.4)	9.6** (4.7)	5.1 (5)	7.9** (3.9)	5.4 (4.5)	-2.5 (3.7)	2 (3.9)	14*** (4.6)	12*** (3.8)
Whether received value	-0.28* (.016)	-0.17 (.015)	.011 (.015)	-0.031** (.015)	-0.0085 (.017)	.023 (.016)	-0.022 (.017)	-0.02 (.016)	.0013 (.015)

This table reports differential estimated treatment effects along dimensions of household characteristics for ration card-level outcomes in endline one (January–March). Each row represents a different primary outcome, and each column grouping represents a different dimension of heterogeneity. The fourth row is an indicator for whether the household received  $> 0$  value. Within each column group, the first column reports the average treatment effect on households that do not satisfy the stated condition, the second column reports the average effect on those that do, and the third column reports the difference in these two effects, all estimated from a single underlying regression that interacts treatment with an indicator for the stated condition. The indicator “HH is upper caste” is equal to one if the household does not belong to Scheduled Caste or Scheduled Tribe. The indicator “HH above median education level” is equal to one if the average number of years of schooling of the two highest-educated household members is above the sample median. The indicator “HH above median annual income” is equal to one if the household’s annual income (as predicted from assets and household characteristics at baseline) is above the sample median. All regressions include strata fixed effects and baseline value of the outcome variable when available. Standard errors clustered at the block level are reported in parentheses, with statistical significance denoted as: \* $p < .10$ , \*\* $p < .05$ , \*\*\* $p < .01$ .

Table A.12: Heterogeneous effects by location characteristics

	FPS in urban area?			Network strength above median?		
	(1) No ( <i>N</i> =3129)	(2) Yes ( <i>N</i> =513)	(3) $\Delta$	(4) No ( <i>N</i> =1565)	(5) Yes ( <i>N</i> =1444)	(6) $\Delta$
Value received (market prices)	-0.74 (13)	-5.9 (19)	-5.2 (23)	-3.1 (13)	-4.2 (16)	-1.1 (18)
Value received (WTA)	30 (23)	-79 (48)	-109** (53)	9.2 (29)	4.4 (29)	-4.8 (37)
Transaction costs	7.1* (3.9)	4.3 (14)	-2.8 (14)	5.9 (5)	1.1 (5.7)	-4.8 (6.5)

This table reports differential estimated treatment effects along dimensions of location characteristics for ration card-level outcomes in endline one (January–March). Each row represents a different primary outcome, and each column group represents a different dimension of heterogeneity. Within each column group, the first column reports the average treatment effect on households that do not satisfy the stated condition, the second column reports the average effect on those that do, and the third column reports the difference in these two effects, all estimated from a single underlying regression that interacts treatment with an indicator for the stated condition. The indicator “FPS in urban area?” is equal to one if the household’s FPS belongs to block that is administratively classified as urban. The indicator “Network strength above median?” is equal to one if the measured signal strength of the Airtel network (which was the most common SIM card type installed in ePOS machines) at the household’s assigned FPS is above the sample median. All regressions include strata fixed effects and baseline value of the outcome variable when available. Standard errors clustered at the block level are reported in parentheses, with statistical significance denoted as: \* $p < .10$ , \*\* $p < .05$ , \*\*\* $p < .01$ .

Table A.13: Heterogeneous effects by machine mode

	Value received (mkt prices)	Value received (WTA)	Transaction costs
	(1)	(2)	(3)
Treatment*Online	1.8 (15)	1 (30)	3.1 (5.2)
Treatment*Offline	-1.6 (22)	-57 (52)	9.2 (9.5)
Treatment*Partial	-37 (29)	-52 (104)	19* (10)
Adjusted R <sup>2</sup>	.20	.06	.08
Control mean	463	1028	41
Observations	9733	9787	3337
% of sample	82	84	86

This table reports differential estimated treatment effects by machine mode assigned to dealers per month for ration card-level outcomes in endline one (January–March). We assign counterfactual machine modes to control FPS’s by assuming they could have received machines operating in the same mode as it was ultimately assigned once treated. This assumption appears reasonable in the sense that the distribution of machine types 6-8 months after the reform was implemented appear similar in both treatment and control areas, with the one exception that the government ended the use of partially online mode in August 2017 and so we impute fewer partially online machines in control. We define the mode in which a machine operated from transaction data as the modal transaction type conducted by that machine and during that month. On average the modal transaction type accounts for 99% of the transactions in a given machine  $\times$  month cell. The unit of analysis for columns 1 and 2 is the ration card-month and for column 3 the ration card. The dependent variable in column 1 is the sum of the values for each commodity, defined as the quantity multiplied by the difference between the median market price of that commodity in control blocks in the same district, and the statutory PDS price for that commodity. The dependent variable in column 2 is the household reported willingness to accept (WTA), constructed as the smallest value  $X$  for which the respondent reported that they would have preferred in cash to the commodities received. The WTA for ration cards that did not receive any ration is set to zero. The dependent variable in column 3 is the total cost incurred in March by the household holding that ration card in purchasing or attempting to purchase PDS commodities, including time and money costs. All regressions include strata fixed effects, and columns 1 and 3 include the baseline value of the outcome variable. Standard errors clustered at the block level are reported in parentheses, with statistical significance denoted as: \* $p < .10$ , \*\* $p < .05$ , \*\*\* $p < .01$ .

Table A.14: Heterogeneous effects by subjective FPS rating

	FPS is Above Median of Implementation Quality		
	No	Yes	Difference
Value Received (market prices)	2 (13)	-5 (15)	-6 (20)
Value Received (WTA)	7 (22)	41 (25)	34 (30)
Transaction Costs	9* (5)	4 (4)	-5 (6)

This table reports differential estimated treatment effects with respect to the (mean) subjective rating of the FPS at baseline. Each row represents a different primary outcome. The first column reports the average treatment effect on households assigned to FPS rated below-median, the second column reports the average effect on those assigned to FPS rated above-median, and the third column reports the difference in these two effects, all estimated from a single underlying regression that interacts treatment with an indicator for FPS category. All regressions include strata fixed effects and baseline value of the outcome variable when available. Standard errors clustered at the block level are reported in parentheses, with statistical significance denoted as: \* $p < .10$ , \*\* $p < .05$ , \*\*\* $p < .01$ .

Table A.15: Decomposition of ration card deletions

	Deleted	Non-deleted	Total	%
	(1)	(2)	(3)	(4)
<i>Admin data</i>				
Unseeded	80,085	133,004	213,089	8.7%
Seeded	64,076	2,172,445	2,236,521	93.1%
Total	144,161	2,305,449	2,449,610	100%
% of overall total	5.9%	94.1%	100%	
<i>Survey data</i>				
Unseeded and ghost	15	6	21	.5%
Unseeded and not ghost	90	142	232	5.9%
Seeded and ghost	11	21	32	.8%
Seeded and not ghost	97	3519	3616	92.7%
Total	213	3688	3901	100%
% of overall total	5.5%	94.5%	100%	

This table reports the decomposition of ration card deletions by Aadhaar seeding status. The top panel shows the results from the universe of ration cards in our 10 study districts, and the bottom panel shows results from our sampled ration cards, for which we show counts adjusted by sampling probability and categorized beneficiaries as based on survey results. A ration card is termed deleted if it was present in the beneficiary list in October 2016 but absent in May 2018. A ration card is termed unseeded if it did not have any Aadhaar number seeded to the card as of October 2016.

Table A.16: Perceptions of the ePOS intervention

	Households	Dealers
<i>Overall, do you prefer ePOS to the old system of manual transactions?</i>	<i>(N=2182)</i>	<i>(N=288)</i>
Strongly disagree	.44	.45
Weakly disagree	.03	.04
Weakly agree	.08	.09
Strongly agree	.45	.42
Did not know/answer	.01	–
<i>Reasons for preference of manual transactions:</i>	<i>(N=1023)</i>	<i>(N=150)</i>
It is cheaper to run FPS operations	–	1
Manual transactions faster	.66	.75
Manual transactions easier to understand	.44	.62
There are no problems with network or software	.28	.74
Anyone can collect rations on my behalf	.43	.06
Could give ration to those who did not have ration cards	–	.03
Dealer to verify amounts purchased	.01	–
It is more profitable	–	.01
Other	.01	.02
<i>Reasons for preference of ePOS enabled transactions:</i>	<i>(N=1165)</i>	<i>(N=137)</i>
ePOS transactions are faster	.54	.60
There is a lower chance of fraud by the FPS dealer	.56	–
The official transaction is equal to what I receive	.14	–
I know my exact ration entitlement and payment amounts	.15	–
Nobody else can collect ration in my name	.38	–
Ration balance carry forward if I don't collect	.06	.13
I receive physical receipts after ePOS transactions	.18	–
I receive text messages after ePOS transactions	.02	–
The dealer calls me to buy ration as he cannot hide supply	.07	–
Better relationship with beneficiaries	–	.64
Beneficiaries are more informed	–	.35
Nobody can steal ration from beneficiary	–	.48
Other	–	.02

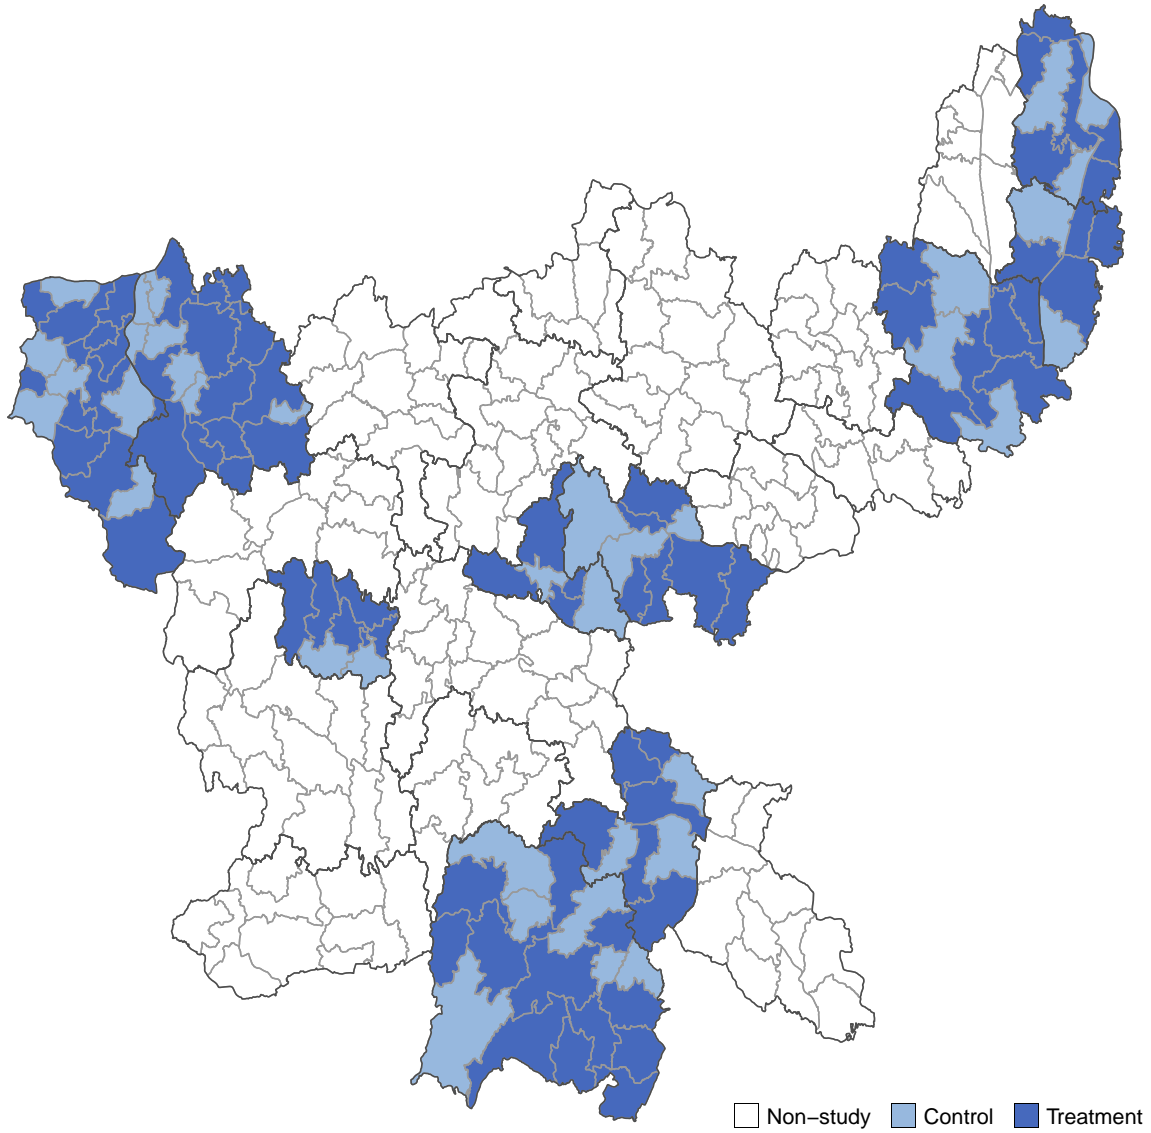

This table reports summary statistics of households' and FPS dealers' stated preferences for and perceptions of the ePOS intervention in March. The sample is restricted to households and dealers in treated blocks. In Panel B the sample is further restricted to respondents who said they strongly or weakly disagreed in Panel A, while in Panel C it is restricted to those who strongly or weakly agreed. Estimates are weighted by inverse sampling probabilities. Some values are missing because the list of options provided to households and dealers differed.

Table A.17: Household years of schooling and probability of ST/SC by seeding status

Outcome	Unseeded	Seeded	Difference	<i>p</i> -value
(1)	(2)	(3)	(4)	(5)
<i>Panel A: Seeded at Baseline</i>				
Years of schooling	7.66	8.58	-0.92***	0.00
SC	0.14	0.15	-0.01	0.71
ST	0.42	0.38	0.04*	0.06
<i>Panel B: Seeded in October 2016</i>				
Years of schooling	7.55	8.41	-0.86*	0.08
SC	0.13	0.14	-0.01	0.73
ST	0.53	0.39	0.14***	0.00

This table shows the distribution of measures of household level years of education (defined as the average number of years in education of the two most educated members in the household) and the proportion of Scheduled Caste and Scheduled Tribes by whether the ration card that household was attached to had at least one Aadhaar number seeded at baseline (Panel A) and in October 2016 (Panel B).

Figure A.1: Blockwise treatment assignment

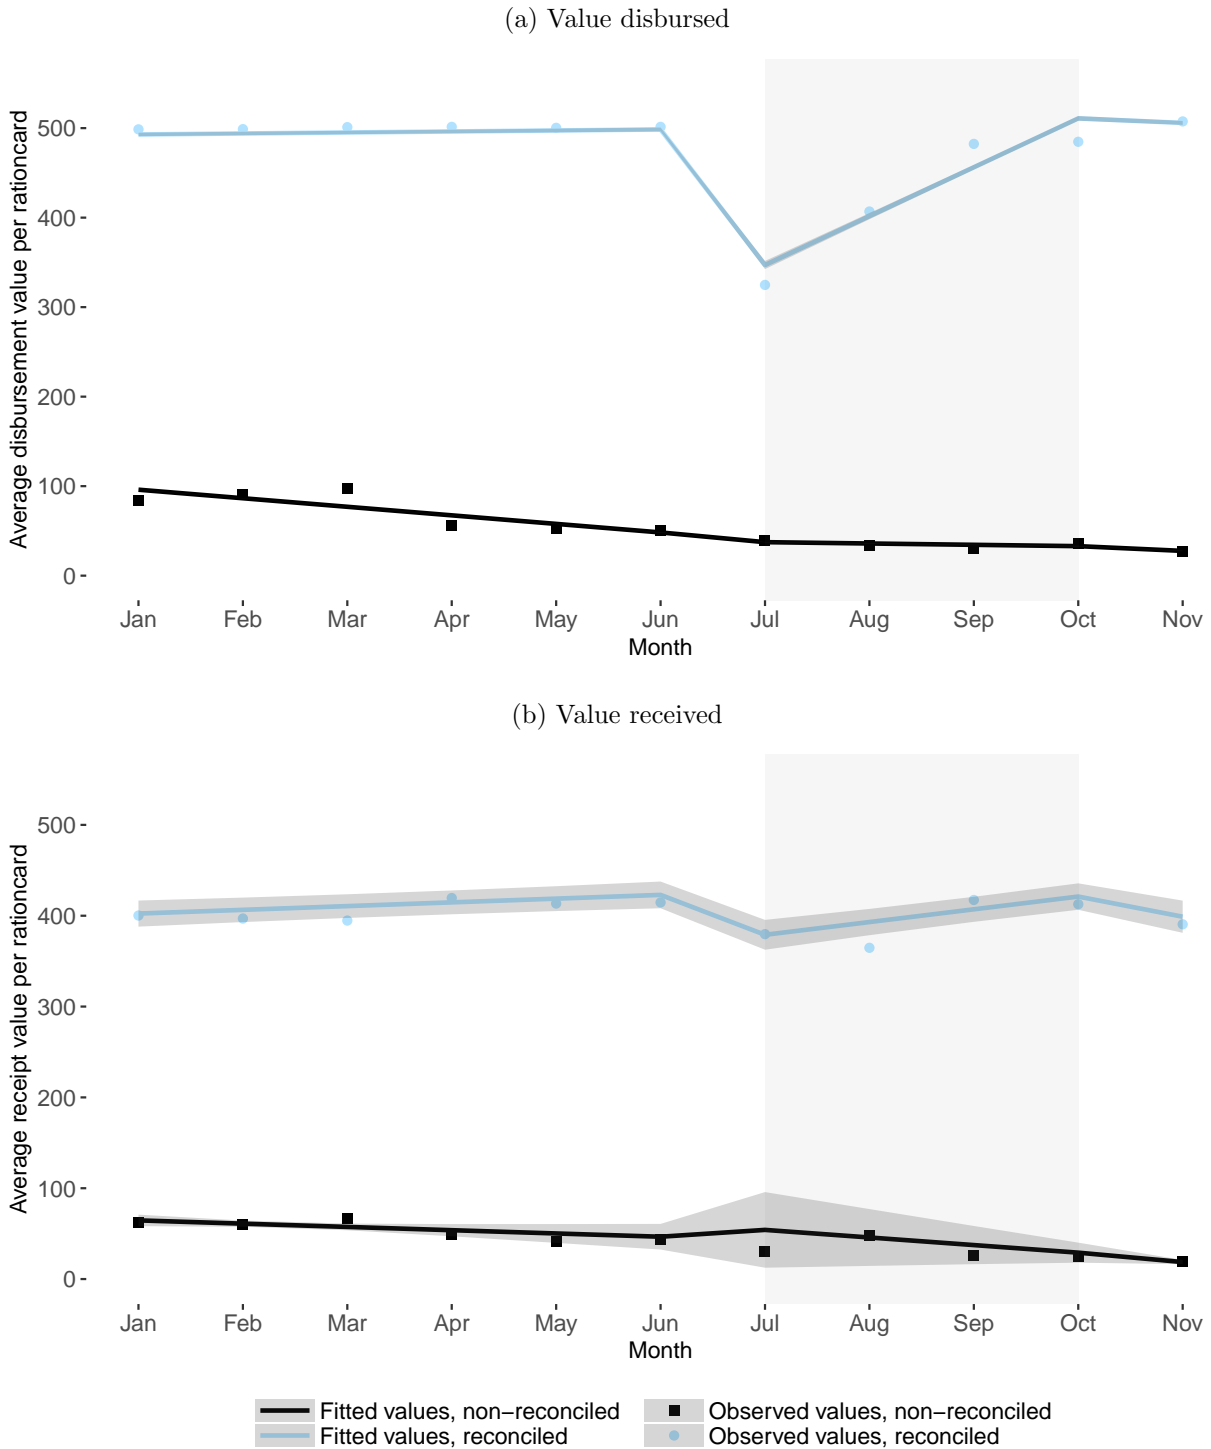

This figure shows the assignment of districts within Jharkhand to study (10) and non-study (14) status, and the assignment of blocks within these districts to treatment and control. Note that four of the census blocks depicted here are further sub-divided for the purposes of PDS administration into an urban and a rural “PDS block;” in these cases we give the entire census block the color corresponding to the treatment status of its larger, rural PDS block.

Figure A.2: Household classification results

This figure classifies the households listed in the ration cards we originally sampled and attempted to survey. “Surveyed” households are those we were able to locate and survey at least once across baseline and the three endline surveys, as opposed to “never surveyed” households. Among the latter, households “exist” if we were able to locate the household but not survey it; are a “ghost” if we could not locate it after an exhaustive search and confirmed with multiple neighbors that it did not exist; and as “unknown” otherwise.

Figure A.3: Effects of reconciliation on value disbursed and received

This figure plots the evolution of the average value of commodities disbursed (Panel A) and received (Panel B) from January to November of 2017. The unit is the ration card-month. Value disbursed is calculated from administration data and value received from our series of endline surveys, using market price data as described in the notes to Table 2. Points represent the raw data, while solid lines represent fitted values obtained by estimating Equation 2. The shaded bands around the latter represent 95% confidence intervals for the fitted values. Values are shown separately for commodities that were (blue) and were not (black) separately subject to reconciliation. The shaded region from July to November indicates the period during which reconciliation was in effect.

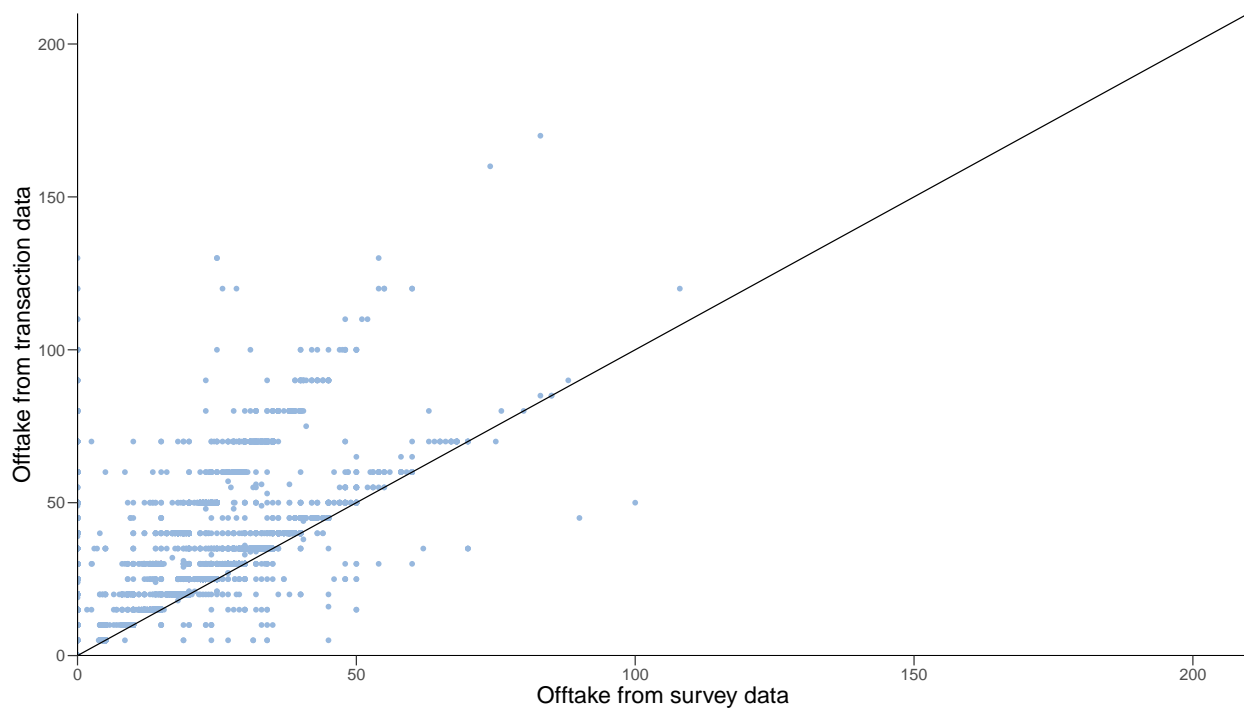

Figure A.4: Recorded grain stock as of June 2017, by treatment status

This figure shows the distribution of grain (i.e. rice and wheat) in kilograms held by FPSs at the end of June 2017 according to government records, separately for shops in treated and control blocks. The unit of observation is the FPS. To increase legibility the distributions are right-censored at the 95th percentile.

Figure A.5: Offtake in survey v.s. administrative records during reconciliation

This figure compares offtake from two data sources: transaction data from ePOS records and survey data from beneficiaries in kilograms. It plots the relationship between ration card-level offtake as recorded in transaction data and reported by beneficiaries.

## B Pre-analysis plan crosswalk

This appendix maps the analysis in the paper to the pre-analysis plans filed for ABBA and for reconciliation.<sup>41</sup> We first describe where each pre-specified exercise is located in the main paper. We then report results from three additional pieces of pre-specified analysis not reported elsewhere. We then provide a list of exhibits in the main paper that are additional to those we pre-specified.

### B.1 Pre-specified analysis in the main paper

Results from estimating the pre-specified equations can be located in the main paper as follows:

#### ABBA PAP

- Equation 1: Tables 2, 7, A.6
- Equation 2: Tables 1, A.1, A.2, A.3, A.4, A.5; Figure A.3
- Equation 3 & 4: Tables 2, 3, 6, A.6, A.7, A.8, A.9, A.10, A.11, A.12, A.13, A.14, A.15
- Equation 5: Table B.7
- Equation 6: Table B.6

#### Reconciliation PAP

- Equation 1 - 4: These equations do not map to a specific table, rather, they show how we calculate disbursement, stock, and carryover of commodities at the FPS-level.
- Equation 5 & 6: Tables 8, A.11, A.12, A.13, A.14
- Equation 7: Tables 7, 8

Exhibits that present summary statistics and that are not mapped to specific equation: Tables A.16, B.1, B.2, B.3, B.4, B.5, E.1; Figures A.6, A.1, A.2, A.5.

### B.2 Pre-specified analysis not in the main paper

The following pre-specified analysis is not reported in the main paper and so included here for completeness:

- Tables B.1, B.2, B.3 and B.4 examine temporal heterogeneity in the impacts of ABBA. We generally see little evidence of trends in the treatment effects.

---

<sup>41</sup>ABBA: <https://www.socialscienceregistry.org/versions/39275/docs/version/document>  
reconciliation: <https://www.socialscienceregistry.org/versions/39274/docs/version/document>

- Table B.5 reports impacts of ABBA on FPS dealer outcomes, controlling for the baseline values of analogous outcomes. The results are very similar to those in Table 6.
- Table B.6 reports the impact of ABBA on government allotment by block, comparing control blocks in treated districts to blocks in non-study districts in order to check if there are any spillover impacts. We do not see any evidence of spillovers through administrative channels.
- Table B.7 tests for spillover effects by regressing market price on the fraction of Fair Price Shops located within  $R$  kilometers of FPS  $f$  and in a different block which are treated, for a range of values of  $R$ .

### B.3 Additional analysis

The following analysis reported in the main paper is in addition to that pre-specified:

- Table A.1, which reports the representativeness of our study area with Jharkhand;
- Panel C of Table 1, which compares measures of program implementation in treated and control areas;
- Table 4, which examines impacts on the extensive margin of value received;
- Table 5, which reports heterogeneous effects by Aadhaar seeding;
- Figure 2, which plots the distribution of value received in treated and control areas;
- Table A.17, which compares household income and education levels between seeded and un-seeded households;
- Table A.2, which compares the dealers we originally sampled to those we added to the sample as households were re-assigned to them;
- Figure 3, which plots the evolution of value disbursed and received in treated and control areas;
- Figure A.4, which plots the distribution of grain stocks as of June 2017 by treatment status.
- Table E.1, which presents first-differenced estimates of disbursement during the reconciliation period.
- Figure E.1, which presents recorded and counterfactual stock and disbursement values throughout 2017.

Table B.1: Effects on value received using alternative specifications

	Total	Rice	Wheat	Sugar	Salt	Kerosene
	(1)	(2)	(3)	(4)	(5)	(6)
<i>Panel A: March only</i>

This table reports alternative specifications for Panel B in Table 2 by reporting models with March data only (Panel A), pooled data with a linear trend (Panel B), and pooled data without baseline lag (Panel C). All regressions include strata fixed effects, and regressions in panels A and B include the baseline value of outcome variable. Standard errors clustered at the block level are reported in parentheses, with statistical significance is denoted as: \* $p < .10$ , \*\* $p < .05$ , \*\*\* $p < .01$ .  $q$  values adjusted to control the false discovery rate across the five commodities are reported in brackets.

Table B.2: Effects on quantities received using alternative specifications

Treatment X Month					6.3 (8.9)
Control mean	1,163	1,157	1,111	1,143	1,143
Observations	3,165	3,122	3,102	9,389	9,389

This table reports a robustness check to Panel B of Table 2 by measuring value as the amount a household is willing to accept in lieu of ration. We report estimates from both the sample that includes (Panel A) and excludes (Panel B) households that did not purchase any ration in a given month. The unit of analysis is the ration card  $\times$  month. The dependent variable is the household reported willingness to accept (WTA), constructed as the smallest value  $X$  for which the respondent reported that they would have preferred in cash to the commodities received. The WTA for ration cards that did not receive any ration is set to zero. All regressions include strata fixed effects. Standard errors clustered at the block level are reported in parentheses, with statistical significance is denoted as: \* $p < .10$ , \*\* $p < .05$ , \*\*\* $p < .01$ .

Table B.5: Effects on dealer expectations controlling for baseline values

	Intends to continue running FPS?		Expected bribes to obtain license?		Expected bribes to renew license?		Profit (self-reported)	
	(1)	(2)	(3)	(4)	(5)	(6)	(7)	(8)
Treatment	.047 (.054)	.024 (.059)	-56,813* (28,922)	-59,841* (33,854)	-111 (123)	-83 (147)	-1,288** (511)	-1,215** (558)
Adjusted R <sup>2</sup>	.098	.14	.3	.27	.053	.035	.098	.083
Control mean	.73	.71	76,590	81,188	565	555	5,891	6,113
Observations	437	366	150	127	370	307	445	370
% of sample		92		32		78		93
Sample	Full	Restricted	Full	Restricted	Full	Restricted	Full	Restricted

This table reports estimated treatment effects on measures of FPS dealers' expectations in March about the future. The unit of analysis is the FPS. The dependent variable in columns 1-2 is an indicator equal to 1 if the dealer responded "yes" when asked whether they intended to continue running an FPS for the next two years and to 0 if they responded "maybe" or "no." The dependent variable in columns 3-4 is the dealer's estimate of the additional money (excluding official fees) someone would have to pay to obtain a new license to operate a FPS. The dependent variable in columns 5-6 is the dealer's estimate of the additional money (excluding official fees) an existing FPS dealer would have to pay to renew his or her license. The dependent variable in columns 7-8 is the dealer's self reported profits from ration sales. For most dealers, profits from ration sales is the same as total profits. In columns 1, 3, 5 and 7 the sample includes all dealers surveyed, including those to whom sampled households switched between baseline and endline; in columns 2, 4, 6 and 8 it includes only dealers drawn in the original sample. All specifications include strata fixed effects and the baseline value (except columns 5 and 6). Standard errors clustered at the block level are reported in parentheses with statistical significance denoted as: \* $p < .10$ , \*\* $p < .05$ , \*\*\* $p < .01$ .

Table B.6: Spillover effect of ABBA on allotment

	Quantity Alloted
Treated District	31,653.34 (22,028.09)
Adjusted R <sup>2</sup>	0.94
Control mean	541,295
Observations	618

This table the impact of being in a treated district on government allotment, comparing control blocks in treated districts to non-study blocks. The dependent variable is quantity allotted by block. Standard errors are clustered at the district level.

Table B.7: Spillover effect of ABBA on reported market prices

	Rice	Wheat	Sugar	Salt	Kerosene

0.65 * $\beta_N$ ( $R = 25$ )	.36 (1.6) [1.00]	1.9 (3.6) [1.00]	-1.4 (2.3) [1.00]	-2.1** (1) [1.00]	1.3 (3) [1.00]
Control mean	19	17	38	8.5	38
Observations	344	109	283	282	251

This table presents the FPS-level spillover effects of reported market prices. Panel A presents household-reported prices and Panel B presents dealer-reported prices. Neighborhood effects are captured by the coefficient  $\beta_N$  on a measure of the intensity with which the area in the neighborhood of a given FPS (but outside its own block) was treated. Each row corresponds to a different radii specification: 15, 20, and 25 kilometers, and the ratio we multiply  $\beta_N$  by is the mean treatment intensity among FPS in treated blocks. Standard errors clustered at the block level are reported in parentheses with statistical significance denoted as: \* $p < .10$ , \*\* $p < .05$ , \*\*\* $p < .01$ .

## C Conceptual framework

This appendix provides a somewhat more detailed and formal discussion of the issues summarized in Section 2.3.

Consider a government that must use an agent to make transfers to a group of  $N$  beneficiaries indexed by  $i$ . In each period  $t$  the government sends a quantity  $q_i^t \in [0, 1]$  to the agent with instructions to deliver  $q_i^t$  to beneficiary  $i$ . Aggregated across beneficiaries, the government sends  $Q^t = \sum_{n=1}^N q_n^t$ . A proportion  $\gamma$  of beneficiaries do not demand the transfer; these may be “ghost beneficiaries” created by the agent solely for the purpose of diversion, but also beneficiaries who have migrated and no longer live in the area, or who do not find it worth the time and cost to collect inferior rationed goods. The other  $1 - \gamma$  of beneficiaries who do demand the transfer negotiate with the agent over how to divide  $q_i^t$ . The government may then receive a signal that is informative about this division. Either way she then chooses the next period’s disbursements  $q_i^{t+1}$  and potentially additional actions affecting the players’ payoffs.

For simplicity we focus on the finite-horizon case  $t = 1, 2$ , and for the most part on the case of a single beneficiary ( $N = 1$ ). We consider the possibility of spillovers across beneficiaries later.

### C.1 The status quo

In this case the government sends  $q_i^t = 1$  every period, receives no informative signals about the outcome, and takes no other actions.

The agent pockets entirely those transfers directed to the share  $\gamma$  of beneficiaries who do not demand them. Consider next the case of one of the  $1 - \gamma$  beneficiaries who does demand the transfer. In the second period, this beneficiary will negotiate with the agent over how to share the value  $q_i^2 = 1$  they have received. Let  $b_i(q) \in [0, q]$  be the amount he receives out of an arbitrary transfer  $q$ ; in equilibrium  $b_i(1)$  will often determine payoffs in which case we will abuse notation by calling  $b_i = b_i(1)$ .  $b_i > 0$  may reflect for example the beneficiary’s ability to complain to local leaders if treated too badly, the agent’s concern for the beneficiary, etc. On the other hand  $b_i < q_i^2$  may reflect for example the dealer’s ability to plausibly claim that he received less than full allotment from the government in the first place, or power asymmetry between the dealer and beneficiary. In the first period, the beneficiary will similarly negotiate with the agent over how to share the value  $q_i^1 = 1$  they have received. Since the future division of rents is determined, the problem is the same and the beneficiary will again receive  $b_i$ .

Overall, the per-period and per-beneficiary average amounts transferred to the agent and

to beneficiaries respectively are

$$v_A = \gamma + (1 - \gamma)(1 - \bar{b}) \quad (4)$$

$$v_B = (1 - \gamma)\bar{b} \quad (5)$$

where  $\bar{b}$  is the bargaining power of the average beneficiary. From the government’s point of view there are two distinct issues. First, some transfers “leak” because the beneficiary for whom they are nominally intended does not demand them – either because he is a ghost or for other reasons. Second, even transfers intended for a beneficiary that demands them leak to the extent that the beneficiary’s influence over the agent is weak (with leakage as high as 100% if  $b_i = 0$ ).

## C.2 Authenticated reconciliation

Now suppose the government introduces a policy of authenticated reconciliation. By this we mean that it (i) asks the agent and the beneficiaries to send reports  $\hat{q}_i^t \in [0, 1]$  quantifying the value transferred to each beneficiary  $i$  in period  $t$ , and that these reports cannot be submitted unless both parties agree to it, and (ii) reconciles its subsequent transfers using this data by setting  $q_i^{t+1} = \hat{q}_i^t$  (with “no message” interpreted as  $\hat{q}_i^t = 0$ .) Note that the requirement that both parties agree to a report captures the fact that after the introduction of ABBA, transaction data could be logged in ePOS devices and remitted to the government only if both parties scanned their fingerprints.

The agent can still divert in period 1 the full amount of transfers sent to the share  $\gamma$  of beneficiaries who do not demand them, but in these cases cannot generate a message  $\hat{q}_i^1$  and thus receives no transfer from the government in period 2. Per-period average leakage thus falls from 1 to 1/2 (and in the unmodelled longer run to 0).<sup>42</sup> Authentication and reconciliation thus unambiguously help to reduce disbursements and leakage due to ghosts, and more generally to beneficiaries who simply do not demand transfers.

Now consider a beneficiary  $i$  who does demand the transfer. The effects of authentication and reconciliation on him are ambiguous for several reasons. First, he now negotiates with the dealer over both (i) a division of the first-period transfer, and (ii) what message to send to the government (which we may simply think of as negotiating directly over  $q_i^2$ ). The efficient outcome is clearly any division of the current transfer and  $q_i^2 = 1$ , while if they fail to agree and thus send no message then  $q_i^2 = 0$ . (Consistent with this, we see that during the

---

<sup>42</sup>In the case where the beneficiary is a real, local resident, the agent might be able to induce him to join in submitting a report  $\hat{q}_i^1 > 0$ . If the beneficiary is truly a “ghost” or migrant, however, biometric authentication precludes this.

reconciliation period the amounts beneficiaries report receiving in our surveys are generally less than those they are recorded as having received in the authenticated transaction data—see Figure A.5.) The beneficiary’s influence over this joint negotiation may be either greater or less than over the simpler problem of dividing the current period’s transfer, which we would interpret as an increase or decrease in  $b_i$ .

Notice that this is not simply because the agent needs to concur with the message: even if the beneficiary could unilaterally choose the message  $\hat{q}_i^t$ , he could not credibly threaten to report  $\hat{q}_i^t = 0$  as this would hurt him in the subsequent period. The key issue is that the government’s sole instrument for punishing the agent for reported diversion is to reduce future disbursements, which also hurts the beneficiary, and thus creates a disincentive for him to report diversion in the first place.

Second, the loss of rents from transfers to the share  $\gamma$  of beneficiaries who do *not* demand transfers may generate spillovers in how the agent approaches the negotiation with those who do. If for example the dealer derives concave utility from his rents (Equation 4) relative to the benefits of avoiding conflict with beneficiaries, then the loss of these rents will make him more willing to extract compensating rents from others.<sup>43</sup> The result is that cracking down on leakage on the accounts of beneficiaries who do not demand transfers “displaces” some of it into other channels. We could represent this formally by extending our notation for the amount beneficiary  $i$  receives to  $b_i(Q, q_i)$ , capturing the fact that it depends not only on  $q_i$ , but also on the amounts disbursed for *other* beneficiaries.

Taking stock, the framework implies that authenticated reconciliation may help to reduce disbursements and leakage, with the size of these effects and their cost in terms of exclusion error depending on (i) the share of beneficiaries on the official rolls who are ghosts or otherwise do not demand transfers, and (ii) the impacts of reconciliation on the (relative) bargaining power of beneficiaries who *do* demand their transfers. We think of other forms of exclusion error, such as beneficiaries’ inability to seed their ration cards, as outside the model and its core set of trade-offs but potentially very important in any given implementation of authenticated reconciliation.

---

<sup>43</sup>In our context, one plausible reason for concave utility in rents is that dealers often pay bribes to obtain PDS licenses (which we present evidence of later) and may have planned to generate a certain amount of rents each month to cover these costs, especially if they have borrowed to make those bribe payments.

## D Empirical methods

### D.1 Randomization

As described above, our study takes place in 10 districts out of the total 24 in Jharkhand. We exclude 1 which had already started ABBA and 6 in which the government was rolling out another related reform, Direct Benefit Transfers for kerosene, which also involved the PDS system and FPSs. We randomly sampled 10 of the remaining 17 within which to randomize the rollout of the intervention. We used stratified random sampling to classify the 17 available districts into 8 (2x2x2) distinct categories using 3 binary variables related to geography and socio-economic status: an indicator for being above/below the median of district (centroid) latitude, an indicator for being above/below the median of district (centroid) longitude, and an indicator for above/below the median of the first principal component of a number of additional variables. We then sampled half of the districts in each category, rounding down to the nearest integer and using probability proportional to size (measured as the number of FPSs) sampling, and lastly sampled additional districts without stratification to reach our target of 10. This design ensures representativeness of the 17 districts in our frame.

Our unit of randomization is the sub-district (“block”), which on average covers 73 FPSs and 96,000 people. We allocated 132 blocks into a treatment arm of 87 blocks and a control arm of 45 blocks, reflecting the government’s preference to delay treatment in as few blocks as possible. Within each study district, we assigned blocks to treatment status as follows: We first divided blocks into rural and urban samples, then stratified them into groups of three by ordering them on the first principal component of three variables related to household size and benefit category: the average number of unique Aadhaar IDs per ration card, the average amount of ration claimed per household in the “priority household” category according to administrative records, and the average amount of ration claimed per household in the (more generous) “Antyodaya Anna Yojana” category. Within each group of 3 blocks we randomly assign 2 to treatment and 1 to control.

### D.2 Sampling

Our sampling procedure for dealers and households uses the administrative database of eligible PDS beneficiaries and their assignment to FPSs from GoJH. We first sampled 3 FPSs in each study blocks for a total of 396 shops, via PPS sampling with “size” defined as the number of ration cards assigned to that FPS. We then sampled households using the list of ration cards assigned to sampled FPSs.

For each sampled FPS we sampled 10 households from the government’s list of PDS

beneficiaries. We define a household here as those individuals listed on a single ration card. We first sampled one village from the catchment area of each FPS using PPS sampling, with “size” defined as the number of ration cards in the village assigned to that FPS. We sampled ration cards using stratified random sampling, with strata including the method by which the household became eligible for the PDS and the benefit category to which the cardholder is entitled. This generated a target sample of 3,960 households. We attempted to interview these households for baseline and three follow-up surveys to create a household-level panel. We ultimately identified and interviewed the corresponding household at least once in 97% of cases. We successfully interviewed 3,410 (86%) of these households at baseline and 3,583 (90%), 3,618 (91%), and 3,562 (90%) at follow-ups 1, 2 and 3, respectively, and interviewed 2,988 (75%) of sampled households in all four rounds.

### D.3 Field data collection protocols

To determine whether a sampled household was a “ghost” (non-existent) household, our field teams followed a stringent procedure. We obtained address details for sampled ration cards from administrative data. Survey enumerators additionally obtained the full set of household member names from the Jharkhand Government PDS System SECC Cardholders list to help distinguish and ascertain the sampled household.

Enumerators first identified and reached the households’ listed village. Many villages are divided into sections that are some distance from each other, called “tolas;” enumerators visited each tola of the village looking for the household. Upon reaching each tola, enumerators asked locals for help in locating the particular household, using the address and the full list of household member names to identify unique households. If they could not find the household, the team would revisit another day to search for the household. If the household could still not be found, the team supervisor would consult with the research monitor and make a subjective determination on whether it is reasonable (according to geographic spread and population density) that all probable hamlets/habitations in the village/urban area were searched to find the household. If all areas could not be searched, we labeled the household as “Not found” (this is *distinct* from a “ghost” categorization).

If all areas had been searched and the household not located, a separate enumerator was assigned the task of contacting one or more of these village leaders to attempt to locate the household: ward member (lowest level elected representative), worker in Anganwadi (childcare) centre, mukhiya (elected head of village). The enumerator spent half a day dedicatedly searching for this household. If no one had ever heard of this household, we had two neighbors (from the local tola/hamlet) record their names, addresses and mobile

numbers for confirmation purposes. We then marked this household as a “ghost” household. Note that we attempted to survey at endline all households selected at baseline, including those we were unable to survey at baseline.

After identifying a sampled household as above and upon approaching a household member, the first thing enumerators did after obtaining verbal consent was to confirm that the sampled ration card actually belonged to the household. Enumerators asked beneficiaries to produce the ration card in order to verify it, and also asked for any other ration cards that the household might own. We captured details of household members listed on the sampled ration card, and clarified that all questions pertained to the sampled ration card only.

After confirming ration card details, we asked for the households’ PDS purchase history from a member with knowledge of these purchases. We asked for purchase records for the previous three months at baseline, endline 1, and endline 3, and the previous five months at endline 2. While ration cards were available as per above, we do not necessarily rely on these for obtaining beneficiary purchase records, since any listing on the ration cards could have easily been manipulated by the dealer at the time of purchase.

Instead, we ask for each commodity, and for each month: the quantity actually purchased, the quantity they are officially entitled to, and how much money they paid for the purchase. We allowed beneficiaries to report either price per unit or the total paid, clearly marking which of the two the amount corresponded to. We also asked about the number of months worth of entitlement this month’s purchase accounted for. Our questions are thus far more detailed than, for example, the National Sample Survey (NSS) that is used for most analysis related to the PDS in India, which only asks about the quantity and value of PDS commodities consumed in the last 30 days.

Note that PDS purchases are extremely salient; beneficiaries go once a month, usually around a particular time of month if not a specific date each month, and buy their entire month’s ration at that time. We therefore did not encounter any significant recall issues.

## E Reconciliation protocol and implementation

The Government of Jharkhand’s stated protocol for disbursing reconciled commodities (i.e. wheat and rice) was given by

$$D_t = \max(0, E_t + C_t - S_{t-1}) \quad (1)$$

$$S_t = S_{t-1} + D_t - O_t \quad (2)$$

$$C_{i,t} = \begin{cases} E_{i,t-1} - (O_{i,t-1} - C_{i,t-1}) & O_{i,t-1} > C_{i,t-1} \\ E_{i,t-1} & O_{i,t-1} \leq C_{i,t-1} \end{cases} \quad (3)$$

Equation 1 defines the amount  $D_t$  to disburse at the beginning of period  $t$  as a function of the amount  $E_t = \sum_i E_{i,t}$  to which recipients assigned to the FPS in period  $t$  were entitled, the amount  $C_t = \sum_i C_{i,t}$  is the total carryover commitment owed to recipients in period  $t$  because they did not collect their entitlement in period  $t-1$ , and the amount of stock  $S_{t-1}$  the government believes the FPS should have been holding at the end of the preceding month. Equation 2 defines the law of motion for stock, which increases with disbursements  $D_t$  and decreases with offtake  $O_t = \sum_i O_{i,t}$  by beneficiaries. Offtake is interpreted as first accruing against carryover commitments from the previous period until these have been exhausted, and then accruing against current period commitments.

To examine the government’s implementation of this protocol we use measures of the aggregates  $S_t$ ,  $E_t$ ,  $C_t$ ,  $D_t$  and  $O_t$  which the National Informatics Commission maintained for each FPS and month, as well as transaction-level data directly from the ePOS devices themselves which record  $O_{i,t}$  for each household and month. This allows us to compare how the amounts disbursed  $D_t$  and records of stock  $S_t$  compare to those we calculate ourselves using the formulae above.

We find two striking patterns. First, while the government’s disbursement policy did hold dealers accountable for accumulated stock to some extent during the reconciliation period, it was far less punitive in practice than its official protocol would have implied. We examine in this in Table E.1, which presents regression estimates of Equation 1. In Column 1 we pool all observations for the four months of reconciliation, so that relationships are estimated off of both time series and cross-sectional variation. In Column 2 we introduce FPS fixed effects to isolate time series variation, since the key regressors (entitlement and stock) may be correlated with unobserved factors such as a dealer’s political influence or importance that influence disbursements. In Columns 3-5 we report first-differenced models month by month to examine trends in adherence over the course of the reconciliation period.

We see that the estimated coefficient on entitlement is large in each model and very close

to 1 by the end of the period, as the official protocol implies it should be. The coefficient on (lagged) stocks, on the other hand, is very small, declining in magnitude from  $-0.07$  to  $-0.03$  by the end of the period (though always significantly different from zero). This implies that a larger stock balance on paper reduced the amount of grain a dealer actually received by a small fraction of the amount the official protocol implies it would, and moreover that this relationship attenuated noticeably over the course of the reconciliation period.

Second, recorded stock balances themselves declined far faster than the records of disbursement and offtake would imply. We illustrate this in the aggregate in the first panel of Figure E.1, where we plot the average recorded stock balance and contrast it with the average balance we obtain by calculating  $S_t$  using the same initial values (in January 2017) but then applying Equation 2 iteratively to obtain subsequent values. We see that the two series track almost exactly until April but diverge sharply starting in May, two months before reconciliation was scheduled to begin. The average recorded balance then falls steadily and actually becomes slightly negative by September—and in fact for many Fair Price Shops recorded balances were *very* negative, indicating that they had (ostensibly) disbursed *more* grain than the government had given to them. In contrast the average calculated balance continues to climb from April to May and then stays more or less flat thereafter.

The consequence of this sharp (and unexplained) reduction in recorded stock is that—even holding fixed the official disbursement protocol in (1)—the government would disburse much more grain to dealers than its official protocol implied. We illustrate this in the second panel of Figure E.1 where we derive the counterfactual amounts of grain the government would have disbursed using Equation 1 and our counterfactual measure of stock. We see that disbursements would have dropped far more drastically in July than they did in practice, and that this gap continues to widen over the course of the reconciliation period. This reflects the fact that according to Equation 2 the average dealer’s recorded stock should have fallen by 6281kg from the end of June to the end of September, while actual average recorded stock fell by 1944kg, with this difference significantly different from zero ( $p < 0.01$ ).

The compound effect of these two deviations from the official protocol was to make reconciliation less punitive than it appeared on paper, and even less so over time. This is consistent with anecdotal evidence that reconciliation met with widespread resistance and pressure for exceptions or adjustments to lessen its impact.

Table E.1: Disbursement during reconciliation

	Total reconciliation period	Total reconciliation period	Jul - Aug	Aug - Sept	Sept - Oct
	(1)	(2)	(3)	(4)	(5)
Entitlement	0.93*** (0.00)	0.89*** (0.01)	0.78*** (0.02)	0.93*** (0.02)	0.99*** (0.01)
Carryover	0.04*** (0.00)	0.00 (0.00)	0.07*** (0.01)	-0.06*** (0.01)	-0.03*** (0.00)
$S_{t-1}$	-0.07*** (0.00)	-0.06*** (0.00)	-0.07*** (0.00)	-0.06*** (0.00)	-0.03*** (0.00)
Estimator	OLS	FPS FEs	FD	FD	FD
Num. obs.	36511	27343	9100	9111	9132

This table presents regression estimates of Equation 1. The unit of analysis is the Fair Price Shop  $\times$  month. The outcome in all columns is the number of kilograms of grain disbursed by the government to that shop in that month (i.e.  $D_t$  in Equation 1). Column 1 pools the four months of reconciliation (July-October). Column 2 adds FPS fixed effects. Columns 3-5 present first-differenced estimates for each pair of months. Standard errors clustered at the block level are reported in parentheses, with statistical significance is denoted as: \* $p < .10$ , \*\* $p < .05$ , \*\*\* $p < .01$ .

Figure E.1: Counterfactual stock and disbursement

Panel A plots the average recorded and counterfactual stock (in kilograms) from January to November 2017. Recorded stock is the value recorded by the National Informatics Commission and provided by the government of Jharkhand. Counterfactual stock is based on our own calculations, where we use the first recorded month's stock, and then apply Equation 2 iteratively to calculate stock for each subsequent month, using the government's records of disbursement and offtake. Panel B plots the corresponding values for disbursement: recorded disbursement is the value disbursed according to government records, and counterfactual disbursement is the amount we calculate using our counterfactual stock series from Panel A, government records of entitlement and carryover, and applying Equation 1.
